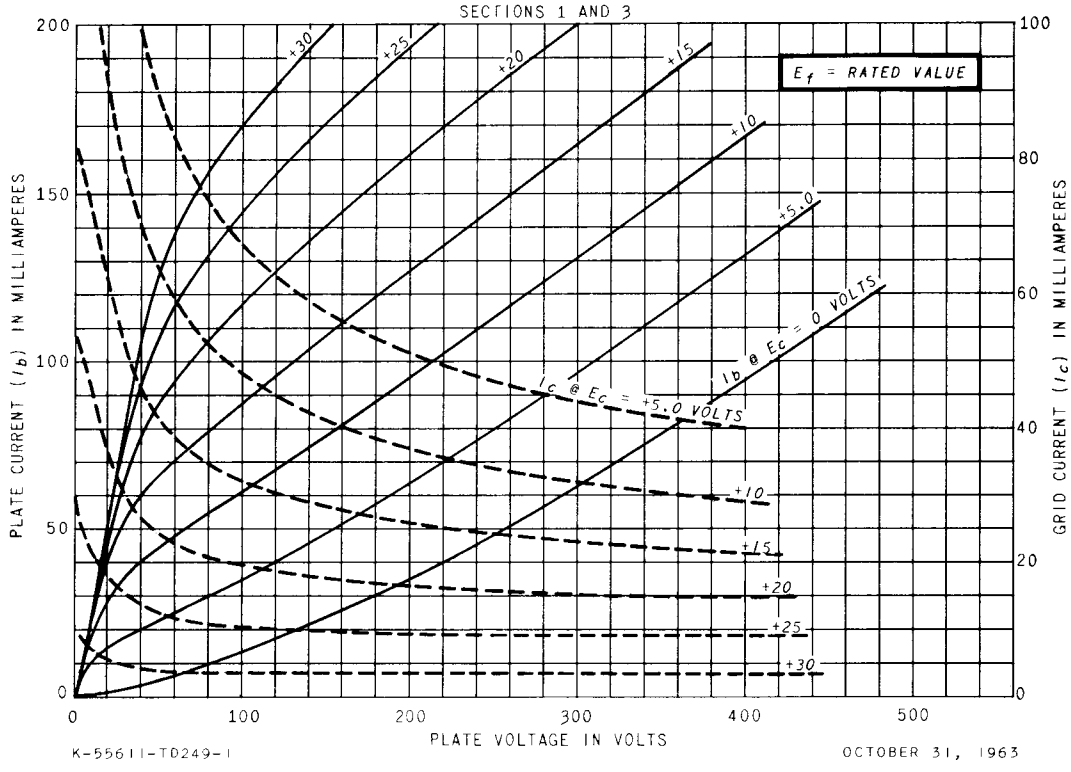
NOTES

* Operated with the heater in series with the heaters of other tubes having the same bogey heater current.

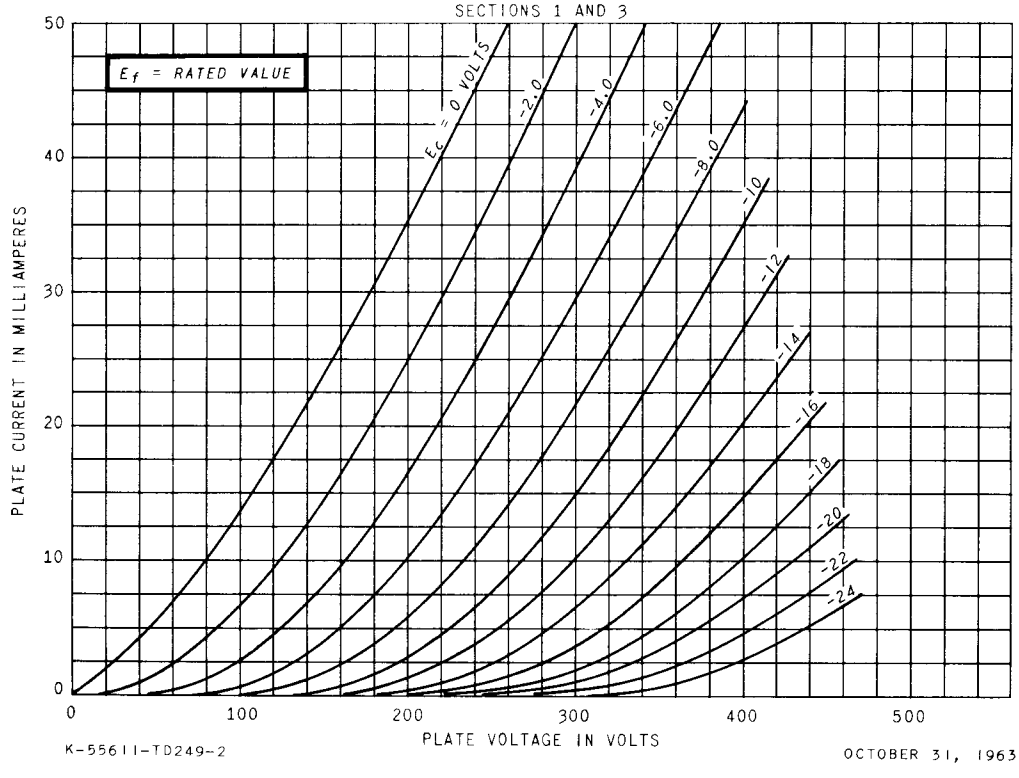
‡ Operated with the heater in parallel with the heaters of other tubes having the same bogey heater voltage.

§ For parallel heater operation, the equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance; for series heater operation, the equipment designer should design the equipment so that heater current is centered at the specified bogey value, with heater supply variations restricted to maintain heater current within the specified tolerance.



¶ Heater current of a bogey tube at Ef = 6.3 volts.

The time required for the voltage across the heater to reach 80 percent of the bogey value after applying 4 times the bogey heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the bogey heater voltage divided by the bogey heater current.



Δ Without external shield.

** In applications where self-bias is used with Section 2, a maximum grid curcuit resistance of 10 megohms is permissible, provided that the plate supply voltage and load resistance are such that the plate dissipation can never exceed 0.5 watts.

6V6-GT—5V6-GT

BEAM PENTODE

DESCRIPTION AND RATING

The 6V6-GT is a beam-power pentode designed for use in the audio-frequency power output stage of television and radio receivers. In this application, it is capable of supplying high power output with high sensitivity, high efficiency, and low third and higher-order harmonic distortion. The 6V6-GT may also be used as a triode-connected vertical-deflection amplifier in television receivers.

Except for heater ratings, the 5V6-GT is identical to the 6V6-GT. In addition, the 5V6-GT, as a result of its controlled heater warm-up characteristic, is especially suited for use in television receivers which employ series-connected heaters. When the 5V6-GT is used in conjunction with other 600-milliampere types which exhibit essentially the same heater warm-up characteristic, heater voltage surges across the individual tubes are minimized during the warm-up period.

MAXIMUM RATINGS

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

6W4-GT - 25W4-GT
Description and Rating

DIODE

FOR TV DAMPING DIODE APPLICATIONS

The 6W4-GT and 25W4-GT are high-vacuum, heater-cathode type diodes each of which is intended for use as the damping diode in the horizontal-deflection circuit of television receivers. Except for heater ratings and direct interelectrode capacitances, the 6W4-GT and 25W4-GT are identical. Each type exhibits a high-perveance characteristic and is capable of withstanding the relatively high pulse voltages normally encountered in this application.

BEAM PENTODE

FOR TV VERTICAL-DEFLECTION AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 6W6-GT is a beam-power pentode intended for service as a triode-connected or pentode-connected vertical-deflection amplifier in television receivers. It is also extremely useful as an audio-frequency power-output tube. In this application the 6W6-GT is capable of delivering relatively large power output at low plate supply voltages and features high power sensitivity and high plate efficiency.

The 6W6-GT, 12W6-GT, and 25W6-GT are alike, except for heater ratings and heater-cathode ratings. The 12W6-GT exhibits a controlled heater warm-up characteristic which makes it especially suited for use in television receivers that employ 600-milliampere, series-connected heaters.

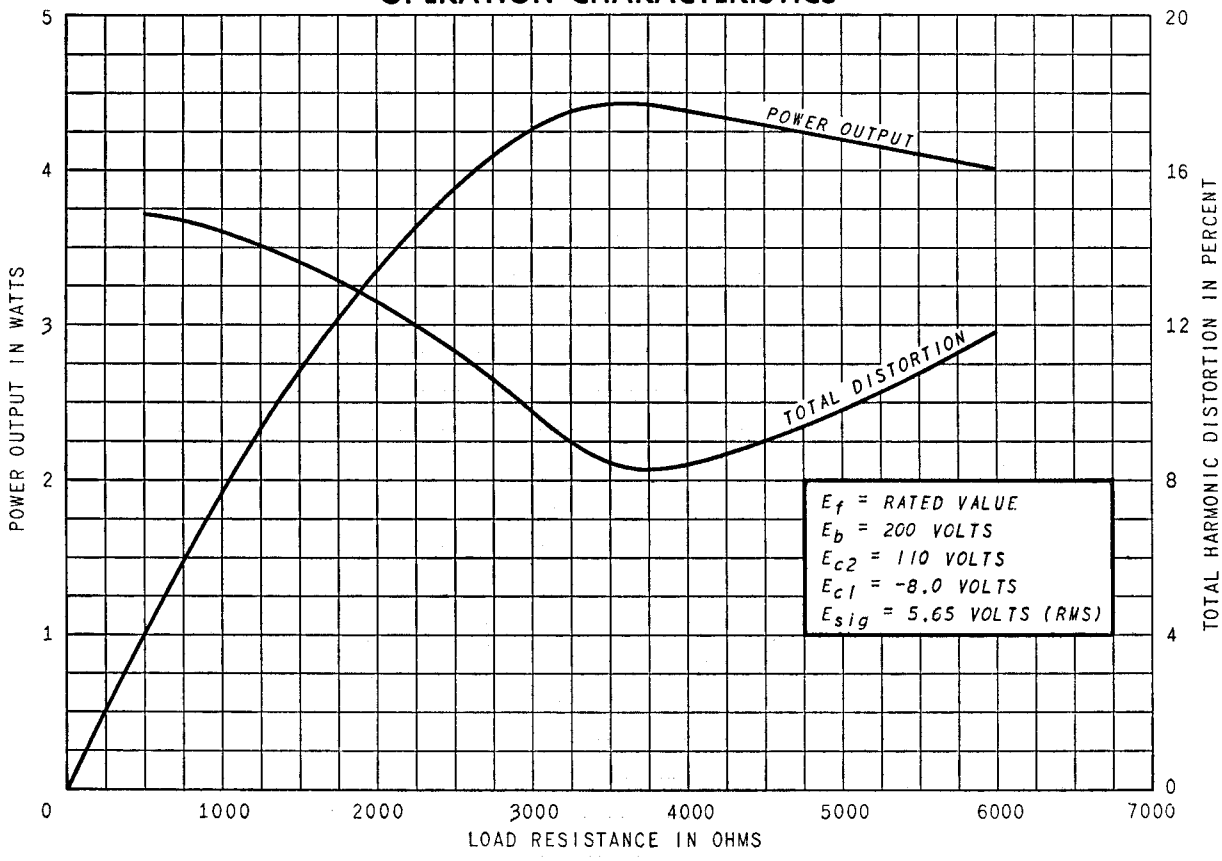
* The time required for the voltage across the heater to reach 80 percent of its rated value after applying 4 times rated heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the rated heater voltage divided by the rated heater current.

† Without external shield.

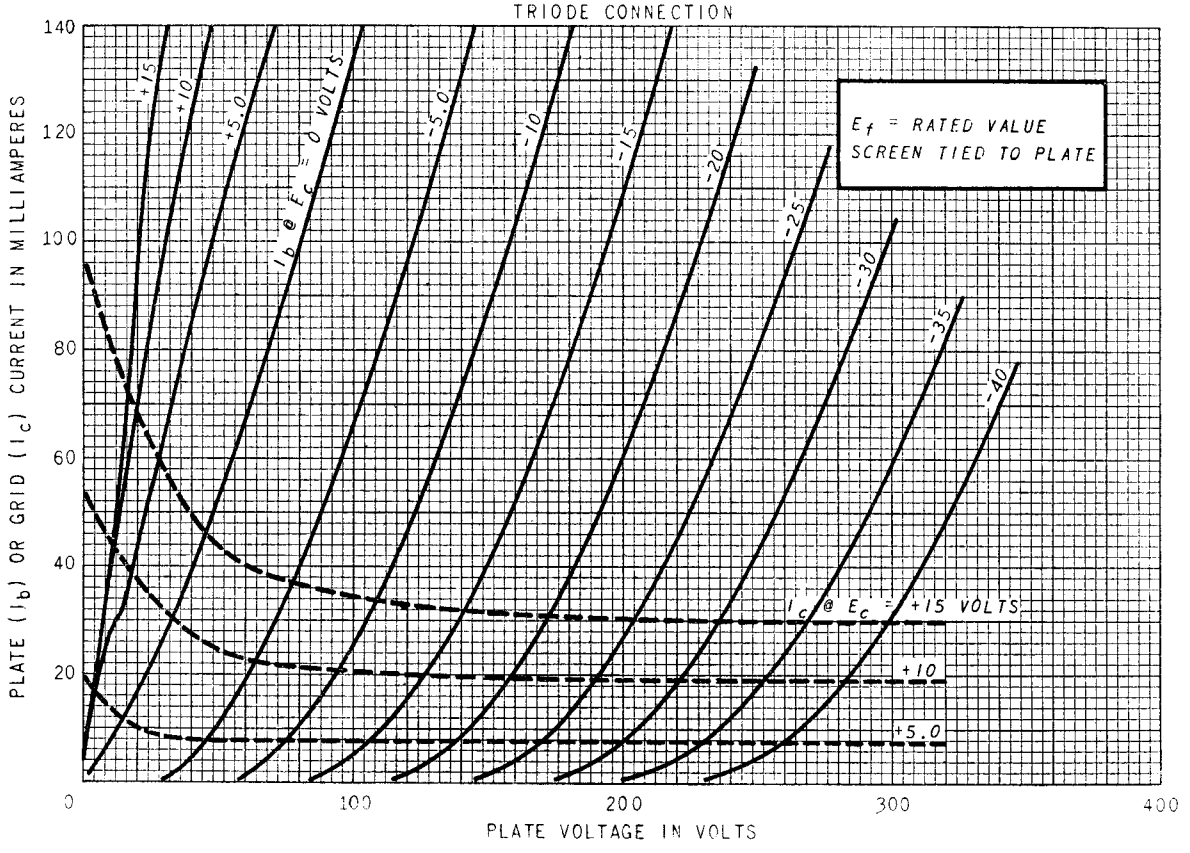
‡ Pin 1 omitted on bases B6-81 and B6-84.



§ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

△ With screen connected to plate.

♦ Value given is to be considered as an Absolute Maximum Rating. In this case, the combined effect of supply voltage variation, manufacturing variation including components in the equipment, and adjustment of equipment controls should not cause the rated value to be exceeded.



ϕ In stages operating with grid-leak bias, an adequate cathode-bias resistor or other suitable means is required to protect the tube in the absence of excitation.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey tube of a specified type as defined by its published data, and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, taking responsibility for the effects of changes in operating conditions due to variations in tube characteristics.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, and environmental conditions.

* When used in automotive service from a 6-volt battery source, the permissible range in heater voltage is from 5.0 to 8.0 volts.

† To simplify the application of the maximum ratings to circuit design, the Design-Maximum ratings are presented in chart form as Rating Charts I, II, and III. Rating Chart I presents the maximum ratings for a-c plate-supply voltage and d-c output current. Rating Chart II provides a convenient method for checking conformance with the maximum steady-state peak-plate-current rating. Rating Chart III offers a convenient method for checking conformance with the maximum transient peak-plate-current rating. Rating Chart I applies to both capacitor-input and choke-input filters, while Rating Charts II and III apply to capacitor-input filters only.

Operating points should be so selected that the boundary limits of a-c plate-supply voltage and d-c output current on Rating Chart I, and maximum d-c output current per plate and rectification efficiency on Rating Chart II, are not exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, and environmental conditions. On Rating Chart I the boundary FAEDG defines the limits for capacitor-input filter operation, and the boundary FABCDG defines the limits for choke-input filter operation.

Rating Chart III shows the minimum value of plate-supply resistance (R_s) required to remain within the transient peak-plate-current rating. The value of R_s should be such that it lies to the left of the line on Rating Chart III at the highest probable value of line voltage.

6X8 — 5X8

TRIODE-PENTODE

FOR VHF CONVERTER APPLICATIONS

DESCRIPTION AND RATING

The 6X8 is a miniature tube incorporating a medium-mu triode and a sharp-cutoff pentode in one envelope. It is designed primarily for use as a combined triode oscillator and pentode mixer in television and FM receivers. Its performance in this application is comparable to that obtainable with a 6AG5 mixer and an oscillator which consists of a single section of a 6J6.

Except for heater ratings and heater-cathode voltage ratings, the 5X8 is identical to the 6X8. The 5X8, as the result of its 600-milliampere heater rating and its controlled heater warm-up characteristic, is particularly suited for use in television receivers which employ series-connected heaters. When the 5X8 is used in conjunction with other 600-milliampere types which exhibit essentially the same heater warm-up characteristic, heater voltage surges across the individual tubes are minimized during the warm-up period.

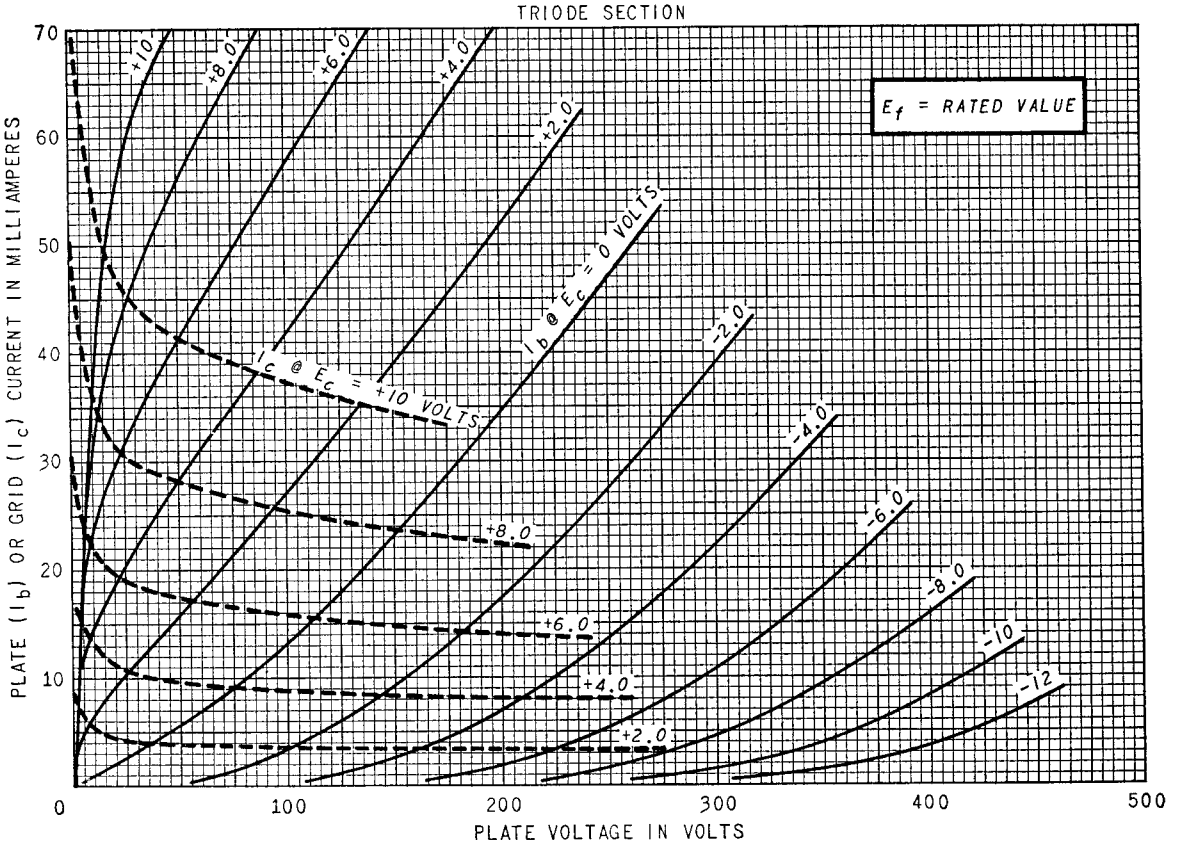
*Heater warm-up time is defined as the time required in the circuit shown at the right for the voltage across the heater terminals (V) to increase from zero to the heater test voltage (V_1). For this type, E = 18.7 volts (RMS or DC), V_1 = 3.73 volts (RMS or DC), and R = 23.5 ohms.

†With external shield (RETMA 315) connected to cathode unless otherwise indicated.



‡With screen connected to plate and suppressor connected to cathode.

§With external shield (RETMA 315) connected to ground.

πIn TV or FM receivers, the oscillator should generally be operated with less power input than shown in the data in order to avoid over-excitation and excessive oscillator radiation.

6Y6-GT

BEAM PENTODE

DESCRIPTION AND RATING

The 6Y6-GT is a beam power pentode primarily intended for use as an audio-frequency power amplifier. It is particularly useful in applications where the available supply voltage is relatively low. The 6Y6-GT differs from the 6Y6-G in only one respect, the straight-sided T-9 construction.

DESCRIPTION AND RATING

The 7AKP19 and 7AKP25 are 4 by 6-inch rectangular faced cathode ray tubes with electrostatic-focus and deflection for radar and oscillographic applications that require a long persistence. They have two electron guns and use post-acceleration. A particular feature of the 7AKP25 is the phosphor which is more burn-resistant than that in the 7AKP19, and which eliminates the initial blue flash characteristic of the P7 phosphor.

FACEPLATE--SPHERICAL, CLEAR
HIGH-RESOLUTION GUN
PERSISTENCE--SHORT
ALUMINIZED SCREEN

DESCRIPTION AND RATING

The 7ARP4 is a 7-inch electrostatic-focus and magnetic-deflection cathode-ray tube for radar and oscillographic applications that requires a short persistence. It has a high-resolution electron gun with a low-voltage focusing lens which provides substantially automatic focus independent of variations in line voltage. The fluorescent screen is aluminized to increase light output, reduce undesirable screen charging, and prevent ion-spot blemish.

DUAL BEAM

ALUMINIZED

DESCRIPTION AND RATING

The General Electric Type 7BH is a 5-1/2 inch square, two beam, electrostatic deflection and focus cathode ray tube having improved deflection sensitivity and display accuracy. The deflection electrode and acceleration electrode connections are brought out through a collar base to minimize lead inductance and capacity.

The screen is aluminized for greater light output and to minimize screen charging effects.

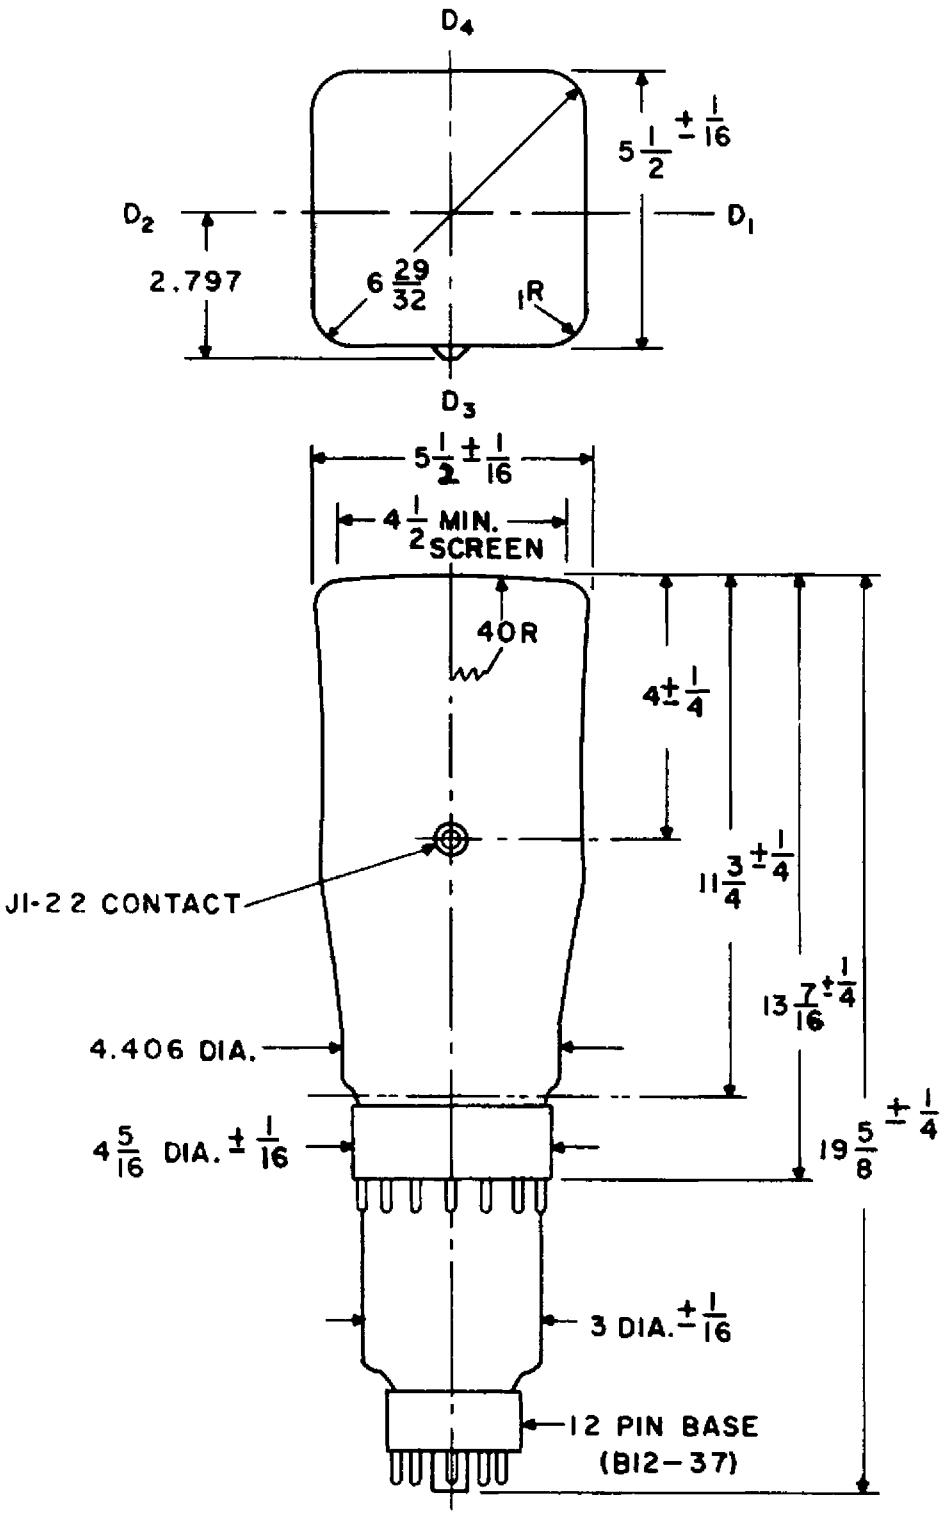
#Visual extinction of the focused, undeflected spot.

##For a beam current of 2 μADC., measured in accordance with MIL-E-1 specifications.

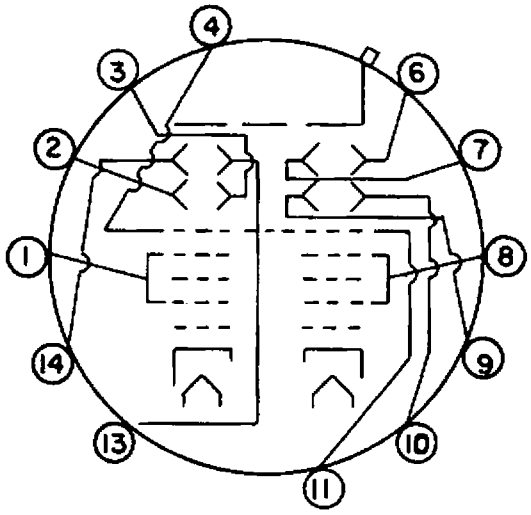
**The edges of a raster pattern whose mean dimensions are 75% of the useful screen width, will not deviate from the mean dimension by more than the specified amount.

ΨWhen one-inch vertical (3D4) traces are superimposed at the center of the tube and deflected horizontally ± 2 inches by voltages proportional to the relative deflection factors, horizontal separation of corresponding points on the lines shall nowhere be greater than 2% of the deflection.



◇The deflection of one beam when balanced DC voltages are applied to the deflection-electrodes of the other beam will not be greater than the indicated value.

◇◇With the free deflecting electrodes connected to the accelerator, and the tube shielded against external influences, the undeflected, focused spot will fall within a 10-mm square centered with respect to the tube face center.



ΨΨIt is recommended that the deflecting-electrode circuit resistances be approximately equal. Higher resistance values up to 5.0 megohms may be used for low beam current operation.

ΨWhen the tube is cut off (no beam current), the post accelerator anode (A_3) will draw 30 μAdc maximum.

FACEPLATE—SPHERICAL, CLEAR
HIGH-RESOLUTION GUN
PERSISTENCE—LONG

DESCRIPTION AND RATING

The 7BP7-B is a magnetic-focus and -deflection direct-view glass cathode-ray tube for oscilloscope and radar applications that require a long persistence. A particular feature of this tube is the high-resolution electron gun which provides a smaller spot size, an improved spot shape, high resolution, and considerable depth of focus.

7EY6

BEAM PENTODE

FOR TV VERTICAL-DEFLECTION AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 7EY6 is a beam-power pentode designed for use as the vertical-deflection amplifier in television receivers that employ 110-degree-deflection picture tubes. Features of the tube include high perveance and high plate dissipation. In addition, the 7EY6 incorporates a controlled heater warm-up characteristic which makes it especially suited for use in television receivers that employ series-connected heaters.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey tube of a specified type as defined by its published data, and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, taking responsibility for the effects of changes in operating conditions due to variations in tube characteristics.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, and environmental conditions.

*The maximum ratings provide a ten-percent safety factor in accordance with the standard design-center system of rating cathode-ray tubes. The tube will withstand the combined effects of variations in line voltage and components provided the maximum design-center values are not exceeded by more than ten percent.

†Anode and grid-No. 3 which are connected together within the tube are referred to herein as anode.

‡Cathode should be returned to one side or to the midtap of the heater transformer winding.

ϕMeasured in accordance with MIL-E-1C, paragraph 4.12.6.2, at an anode current of 100 microamperes.

♥The center of the undeflected, unfocused spot will fall within a circle of 12 millimeters radius concentric with the tube face.

§Brightness and focus quality decrease with decreasing anode voltage. In general, the anode voltage should not be less than 5000 volts.

πFor visual extinction of undeflected focused spot.

▲For RETMA focusing coil No. 106 with distance from the yoke reference line to center of air gap equal to 2¾ inches.

—PRODUCT INFORMATION—

8AC10

Compactron Triple Triode

The 8AC10 is a compactron containing three high-mu triodes. It is designed for use primarily as a color-difference amplifier in color television receivers.

Except for heater characteristics and ratings, the 8AC10 is identical to the 6AC10.

GENERAL

ELECTRICAL

Cathode - Coated Unipotential

Heater Characteristics and Ratings		
Heater Voltage, AC or DC*	8.4	Volts
Heater Current‡	0.45±0.03	Amperes
Heater Warm-up Time, Average§	11	Seconds

NOTES

* Heater voltage for a bogey tube at If = 0.45 amperes.

‡ The equipment designer should design the equipment so that heater current is centered at the specified bogey value, with heater supply variations restricted to maintain heater current within the specified tolerance.

§ The time required for the voltage across the heater to reach 80 percent of the bogey value after applying 4 times the bogey heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the bogey heater voltage divided by the bogey heater current.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

Grid-Number 1 Circuit Resistance			
With Fixed Bias	0.1	0.5	Megohms
With Cathode Bias	0.25	1.0	Megohms

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

CHARACTERISTICS AND TYPICAL OPERATION

TELEVISION PICTURE TUBE

DESCRIPTION

The 8AP4-A is a magnetic-focus and -deflection, direct-view picture tube for television applications. It provides a 5¼- by 7-inch picture. Features of this tube are a metal-cone envelope, an electron gun designed to be used with an external ion-trap magnet, and a high-quality, neutral-density faceplate which increases picture contrast and detail under high ambient light conditions.

TECHNICAL INFORMATION

GENERAL

Electrical

Heater voltage	6.3	volts
Heater current	0.6 ± 10%	ampere
Focusing method—magnetic		
Deflecting method—magnetic		
Deflecting angle, approximate	54	degrees
Phosphor—P4		
Fluorescence—white		
Persistence—medium		
Faceplate—neutral density		
Light transmission, approximate	76	percent
Direct interelectrode capacitances, approximate		
Cathode to all other electrodes	5	uuf
Grid—No. 1 to all other electrodes	6	uuf

GE Electronic TUBE

GENERAL ELECTRIC

TECHNICAL INFORMATION (CONT'D)

Mechanical

Over-all length	$14\frac{1}{4} \pm \frac{3}{8}$	inches
Greatest diameter of bulb	$8\frac{1}{2} \pm \frac{3}{16}$	inches
Picture dimensions (with rounded sides)		
Width	7	inches
Height	$5\frac{1}{4}$	inches

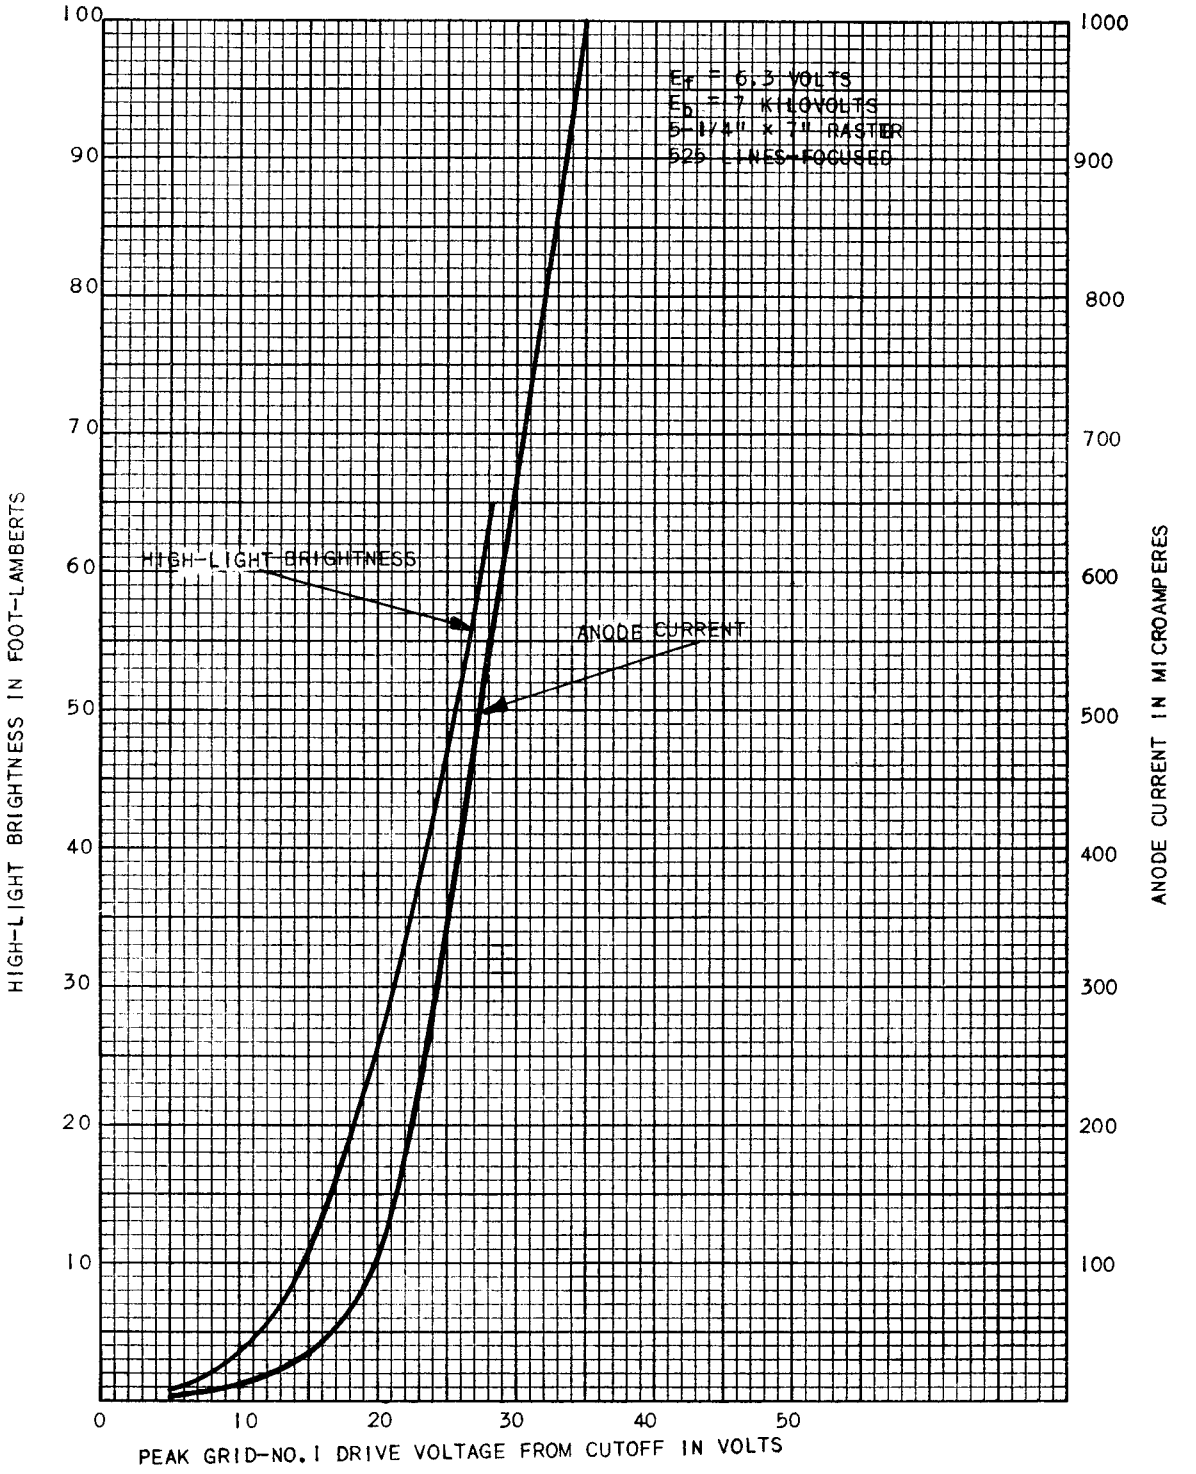
Anode contact—metal cone rim
Base—small-shell duodecal 5-pin, B5-57
Basing—12H

MAXIMUM RATINGS Design Center Values

Anode voltage	9000 max	volts d-c
Grid—No. 1 voltage		
Negative—bias value	125 max	volts d-c
Positive—bias value	0 max	volts d-c
Positive—peak value	2 max	volts
Peak heater—cathode voltage*		
Heater negative with respect to cathode		
During warm-up period not to exceed 15 seconds	410 max	volts d-c
After equipment warm-up period	140 max	volts d-c
Heater positive with respect to cathode	140 max	volts d-c

RECOMMENDED OPERATING CONDITIONS

Anode voltage (average brightness = 20 foot-lamberts)	7000	volts
Grid—No. 1 voltage**	−27 to −63	volts
Focusing-coil current (RTMA coil No. 106 at $3\frac{1}{4}$-inches), approximate	115	milliamperes
Ion-trap field intensity***, approximate	45	gausses



MAXIMUM CIRCUIT VALUES

Grid—No. 1 circuit resistance	1.5 max	megohms

*Cathode should be returned to one side or to the midtap of the heater transformer winding.
**For visual extinction of undeflected focused spot.
***Single-field ion-trap magnet adjusted to optimum position.

Compactron Triode-Twin Pentode

8BA11

The 8BA11 is a compactron triode - twin pentode. The medium-mu triode section may be used as a vertical-deflection oscillator. The twin pentode incorporates separate plates and number-3 grids for the two sections together with a common screen, number-1 grid, and cathode. This section is intended for combined sync-AGC applications in television receivers.

Except for heater characteristics, the 8BA11 is identical to the 6BA11.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

MAXIMUM RATINGS

DESIGN-MAXIMUM VALUES, Each Section

Plate Voltage	330	Volts
Screen Supply Voltage	330	Volts
Screen Voltage - See Screen Rating Chart		
Positive DC Grid-Number 1 Voltage	0	Volts
Plate Dissipation	3.1	Watts
Screen Dissipation	0.65	Watts
Heater-Cathode Voltage		
Heater Positive with respect to Cathode		
DC Component	100	Volts
Total DC and Peak	200	Volts
Heater Negative with respect to Cathode		
Total DC and Peak	200	Volts
Grid-Number 1 Circuit Resistance		
With Cathode Bias	0.25	Megohms

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

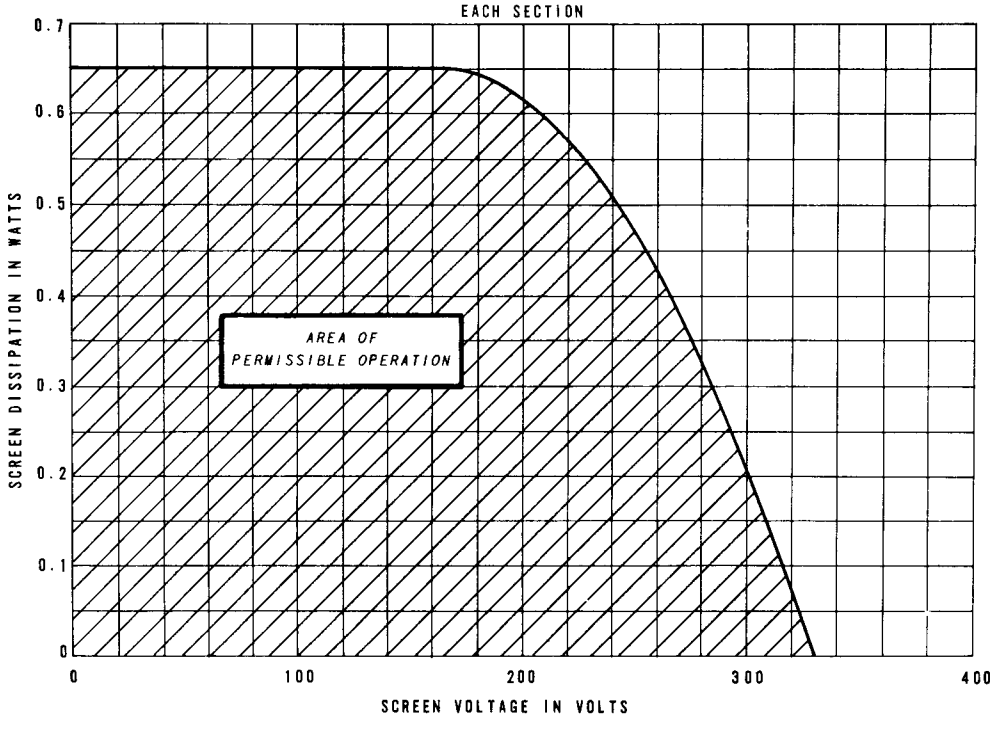
The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

CHARACTERISTICS AND TYPICAL OPERATION

AVERAGE CHARACTERISTICS, Each Section

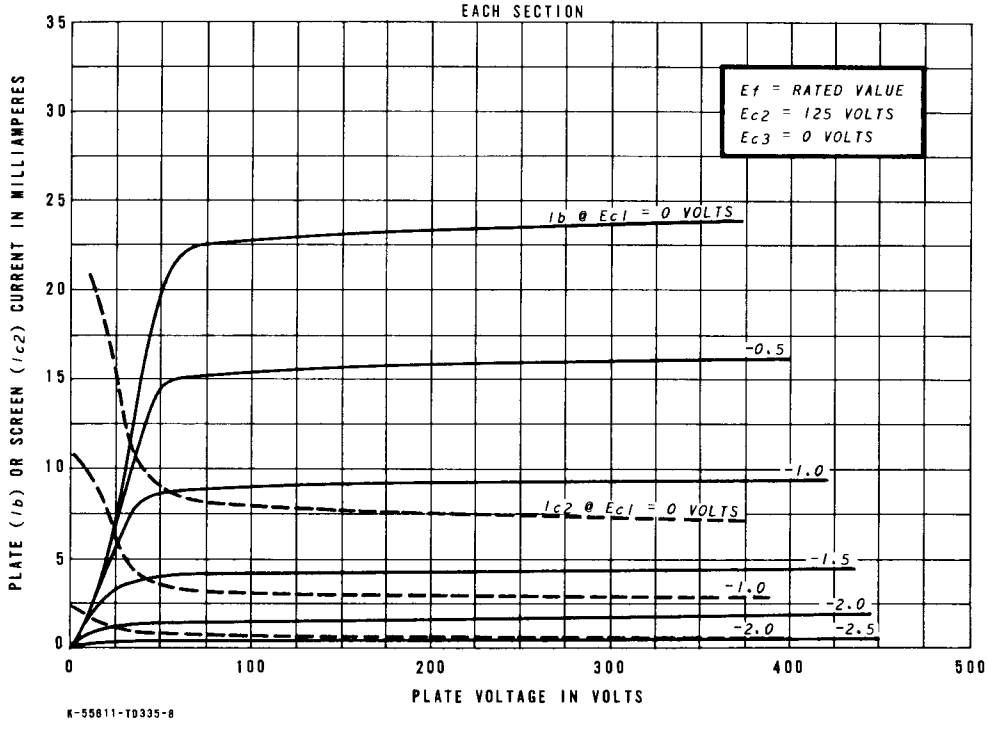
Plate Voltage	125	Volts
Suppressor, Connected to Cathode at Socket		
Screen Voltage	125	Volts
Cathode-Bias Resistor	56	Ohms
Plate Resistance, approximate	0.2	Megohms
Transconductance	13000	Micromhos
Plate Current	11	Milliamperes
Screen Current	3.8	Milliamperes
Grid-Number 1 Voltage, approximate		
Ib = 20 Microamperes	−3	Volts

NOTES



★ Heater voltage for a bogey tube at If = 0.6 amperes.

● The equipment designer should design the equipment so that heater current is centered at the specified bogey value, with heater supply variations restricted to maintain heater current within the specified tolerance.



♦ The time required for the voltage across the heater to reach 80 percent of the bogey value after applying 4 times the bogey heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the bogey heater voltage divided by the bogey heater current.

§ With external shield (EIA 309) connected to cathode of section under test.

70-DEGREE DEFLECTION ANGLE	ALUMINIZED SCREEN

DESCRIPTION AND RATING

The 8RP4 is an eight inch electrostatic focus and magnetic deflection cathode ray tube for monitor use in closed circuit television, studio broadcasting, and industrial applications. Outstanding features include a 70° deflection angle for a better center to edge focusing characteristic with a reduced deflection power requirement and a high resolution, non-ion trap electron gun.

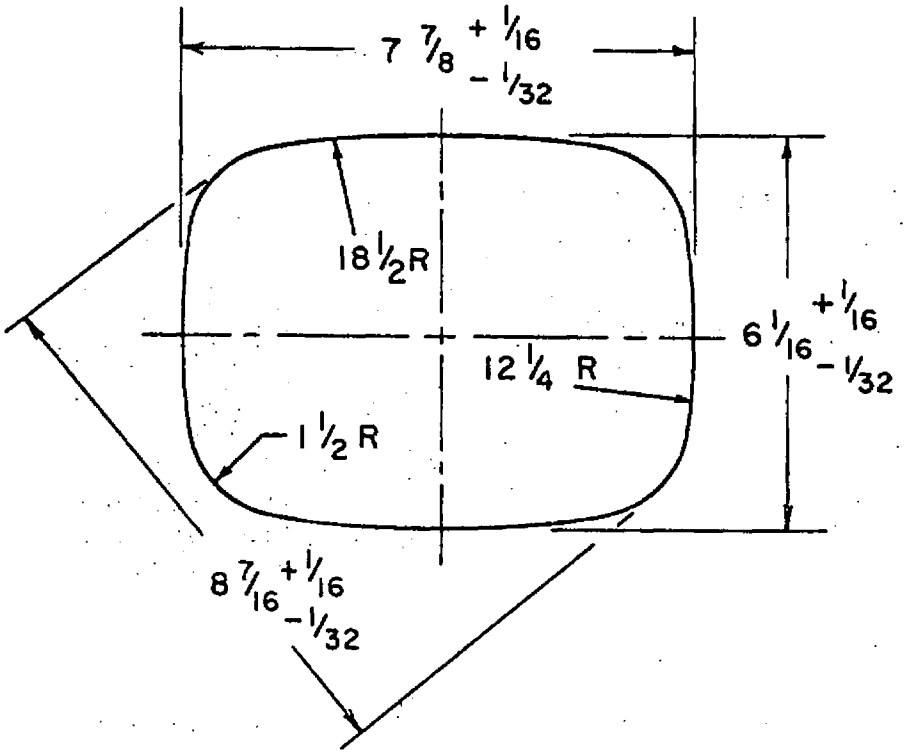
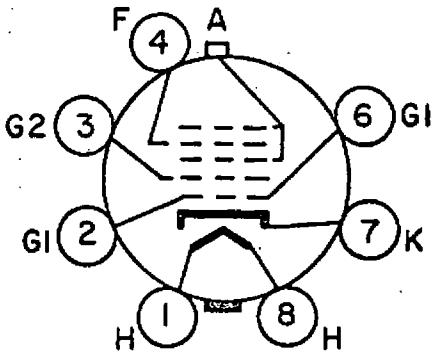
NOTES:

\+ The maximum ratings provide a ten percent safety factor in accordance with the standard design center system of rating cathode ray tubes. The tube will withstand the combined effects of variations in line voltage and components provided the maximum design center values are not exceeded by more than ten percent.



* For visual extinction of focused raster.



+++ Measured in accordance with MIL-E-1 paragraph 4.12.6.2 at an anode current of 100μa.

WARNING:

If this tube is operated at voltages in excess of 16,000 volts, x-ray radiation shielding may be necessary to avert possible danger of personal injury from prolonged exposure at close range. The protective face-viewing window of apparatus using tubes of this type may provide such a safeguard. If the radiation measured in contact with this window does not exceed 6.25 milliroentgens per hour, the window will normally provide adequate protection.

DESCRIPTION AND RATING

The 10BP4-A is a magnetic-focus and deflection, direct-view picture tube for television applications. It provides a 9⅛- by 6¾-inch picture. Features of this tube are an electron gun designed to be used with an external ion-trap magnet for the prevention of ion-spot blemish, and a high-quality gray faceplate which increases picture contrast and detail under high-ambient-light conditions. An external conductive coating serves as a filter capacitor when grounded.

Electronic TUBES

10C8

TRIODE-PENTODE

DESCRIPTION AND RATING

The 10C8 is a miniature triode-pentode designed for use in compact, 300-milliampere, series-string television receivers. The pentode section may be used as a general-purpose amplifier or as a triode-connected vertical-deflection amplifier. The high-mu triode section is suitable for use as a vertical oscillator, AF voltage amplifier, or as a sync separator, clipper, or amplifier.

The 10C8 has a controlled heater warm-up characteristic as required for use in television receivers that employ series-connected heaters. Other features of the tube include relatively small size, low power requirements, and high performance capabilities at the low d-c supply voltages normally available in these applications.

Design-Maximum Ratings are the limiting values expressed with respect to bogie tubes at which satisfactory tube life can be expected to occur for the types of service for which the tube is rated. Therefore, the equipment designer must establish the circuit design so that initially and throughout equipment life no design-maximum value is exceeded with a bogie tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, and environmental conditions.

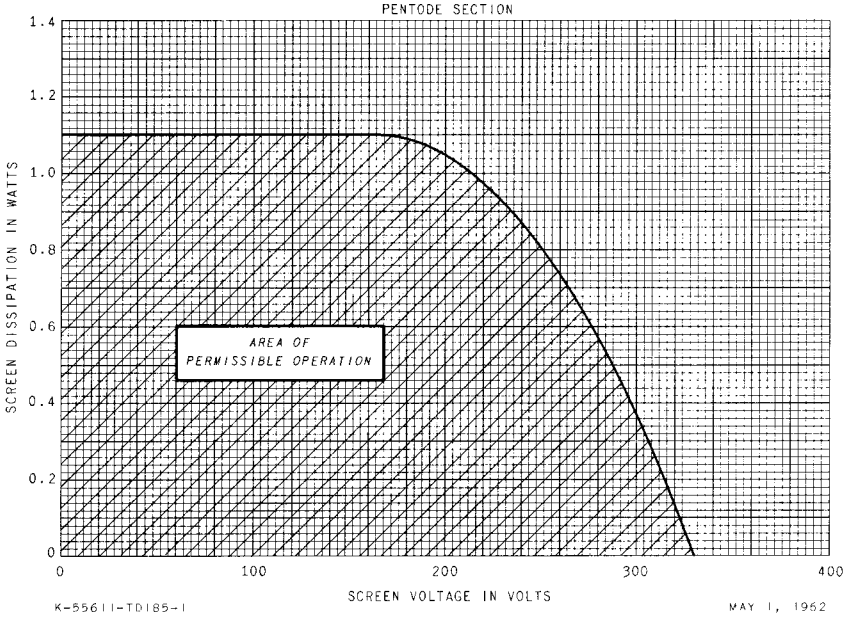
FOOTNOTES

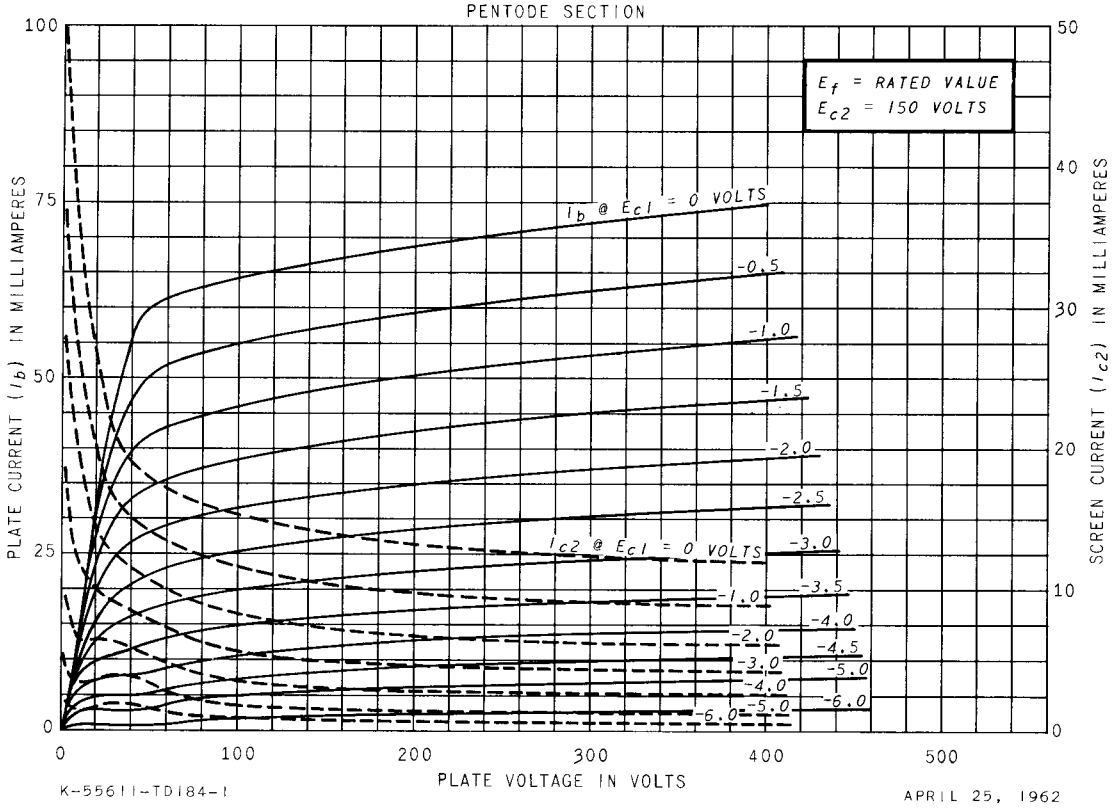
* Heater voltage for bogey tube at If = 0.45 amperes.



† For series heater operation, the equipment designer should design the equipment so that heater current is centered at the specified bogey value, with heater supply variations restricted to maintain heater current within the specified tolerance.

‡ The time required for the voltage across the heater to reach 80 percent of its rated value after applying 4 times rated heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the rated heater voltage divided by the rated heater current.

§ Without external shield.



¶ Applied for short interval (two seconds maximum) so as not to damage tube.

CATHODE RAY TUBE

11 INCH, RECTANGULAR, GLASS	FACEPLATE -- SPHERICAL GRAY
FOCUS -- ELECTROSTATIC	INTEGRAL PLASTIC IMPLOSION BARRIER
DEFLECTION -- MAGNETIC	ALUMINIZED SCREEN
110 DEGREE DEFLECTION	EXTERNAL CONDUCTIVE COATING

----------DESCRIPTION AND RATING----------

The 11AP4 is a 11 inch electrostatic-focus and magnetic deflection glass lightweight picture tube employing an integral plastic implosion barrier. Other outstanding features include a short over-all length, a small neck diameter and a non ion trap gun designed for operation at an intermediate Grid no. 2 voltage for use in cathode-drive circuits. The fluorescent screen is aluminized to increase light output and reduce undesirable screen charging. An external conductive coating is provided to serve as a filter capacitor when grounded.

Anode Contact Aligns with Base Pin No. 4 ± 30 degrees	

RATINGS (Design Maximum System)

Unless otherwise specified, voltage values are positive and measured with respect to Grid No. 1.

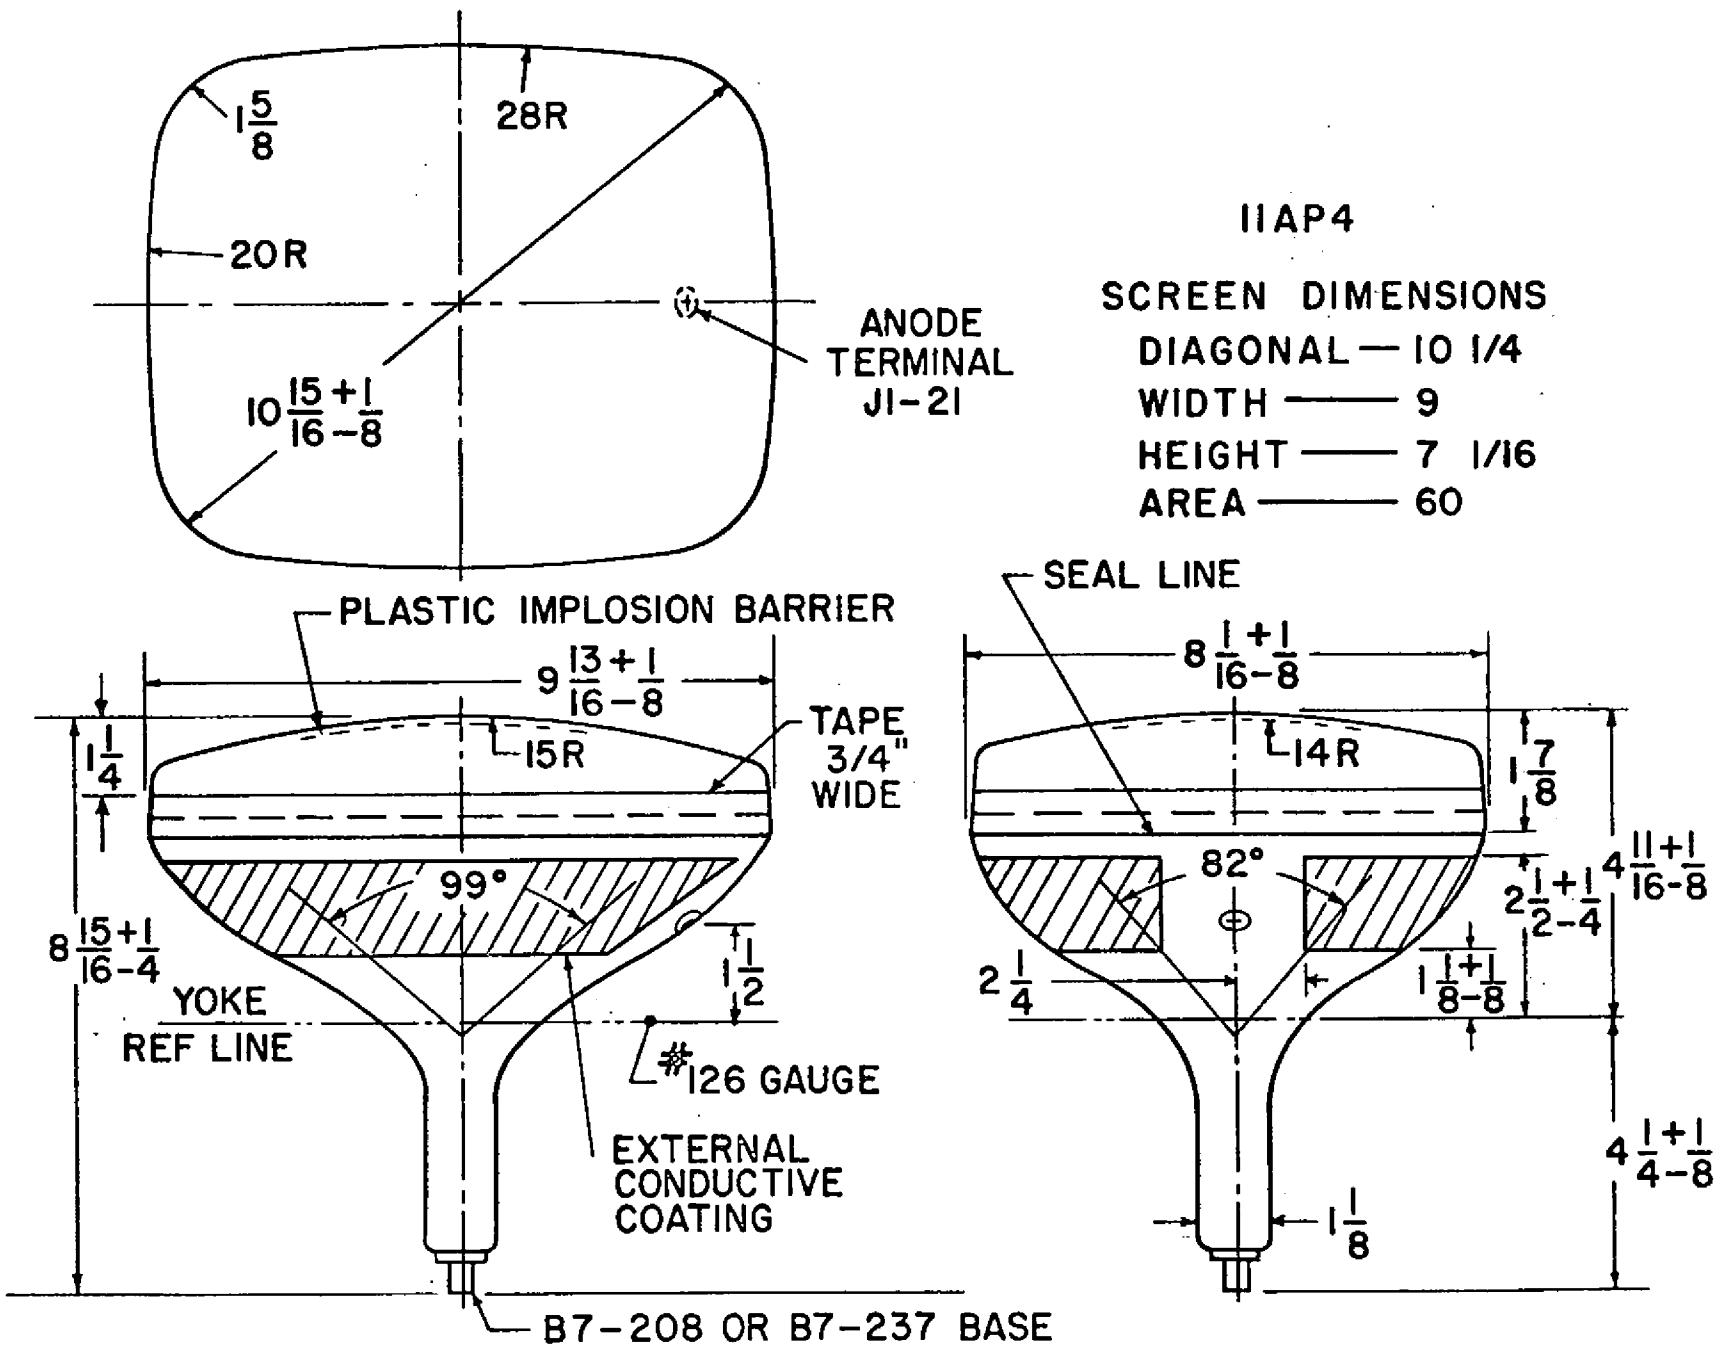
Maximum Anode Voltage	15,000 volts
Minimum Anode Voltage	9,000 volts
Maximum Grid #4 (Focusing Electrode) Voltage	-500 to +1000 volts
Minimum Grid #2 Voltage	100 volts
Maximum Grid #2 Voltage	250 volts
Cathode Voltage	
Maximum Positive Value	140 volts DC
Maximum Positive Peak Value	200 volts
Maximum Negative Value	0 volts DC
Maximum Negative Peak Value	2 volts
Maximum Heater Voltage	6.9 volts
Minimum Heater Voltage	5.7 volts
Maximum Heater-Cathode Voltage	
Heater Negative with respect to Cathode	
During Warm-Up period not to exceed 15 sec.	410 volts
After equipment warm-up period	200 volts
Heater Positive with respect to Cathode	200 volts

TYPICAL OPERATING CONDITIONS (Cathode-Drive Service)

Anode Voltage	11,000 volts DC
Grid #4 Voltage (Focusing Electrode, Notes 2&3)	250 volts DC
Grid #2 Voltage	150 volts DC
Cathode to Grid #1 Voltage for cut-off (note 1)	31 to 49 volts

MAXIMUM CIRCUIT VALUES

Maximum Grid #1 Circuit Resistance	1.5 max. megohm
Grid #2 Circuit Resistance	0.1 min. megohm
Focusing Electrode Circuit Resistance	0.1 min. megohm



Protective resistance in Grid #2 and focusing electrical circuits is advisable to prevent damage to tube. If applicable, one resistor common to both circuits may be used.

NOTES:

1. Visual extinction of focused raster.

2. With the combined Grid #1 bias voltage and video-signal voltage adjusted to give an anode current of 150 ua on a 9" x 7-1/16" pattern from RCA 2F21 monoscope or equivalent.

3. Individual tubes will have satisfactory focus at some value between 0 and 400 volts.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

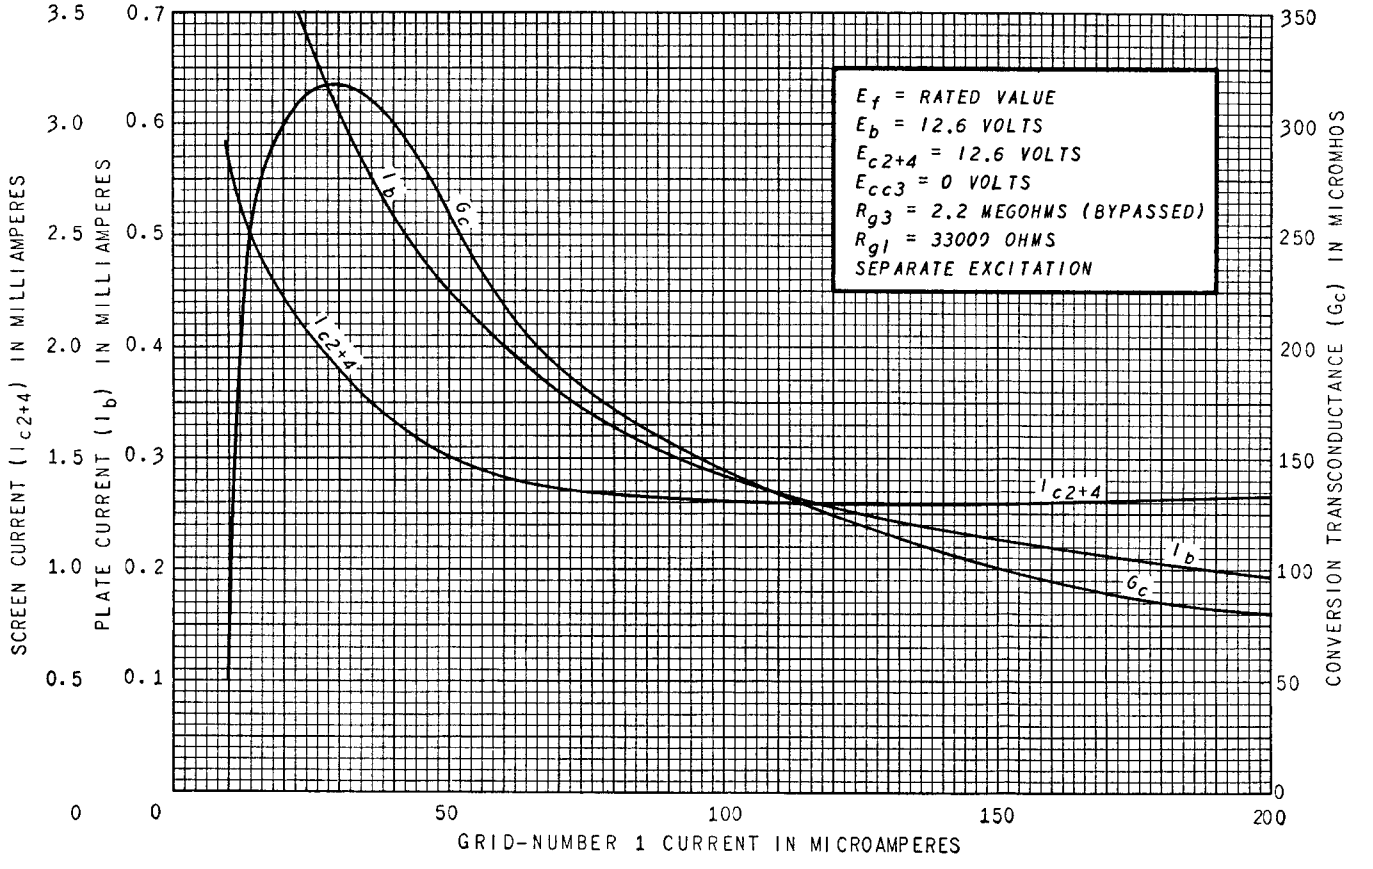
* When used in automobile service from a 12-volt source, under no circumstances should the heater voltage be less than 10.0 volts or more than 15.9 volts. These extreme variations in heater voltage may be tolerated for short periods; however, operation at or near these absolute limits in heater voltage necessarily involves sacrifice in performance at low heater voltage and in life expectancy at high heater voltage. Equipment reliability can be significantly increased with improved supply-voltage regulation.

† With external shield (RETMA 316) connected to pin 2.



‡ Between grid-number 1 and grids number 2 and 4 connected to plate.

PRODUCT INFORMATION

Compactron Dissimilar Double Pentode

12AE10

The 12AE10 is a compactron containing a sharp-cutoff, dual-control pentode (Section 2) and a power pentode (Section 1). The dual-control pentode is intended for use as an FM detector and the power pentode as an audio-frequency output amplifier in television receivers.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

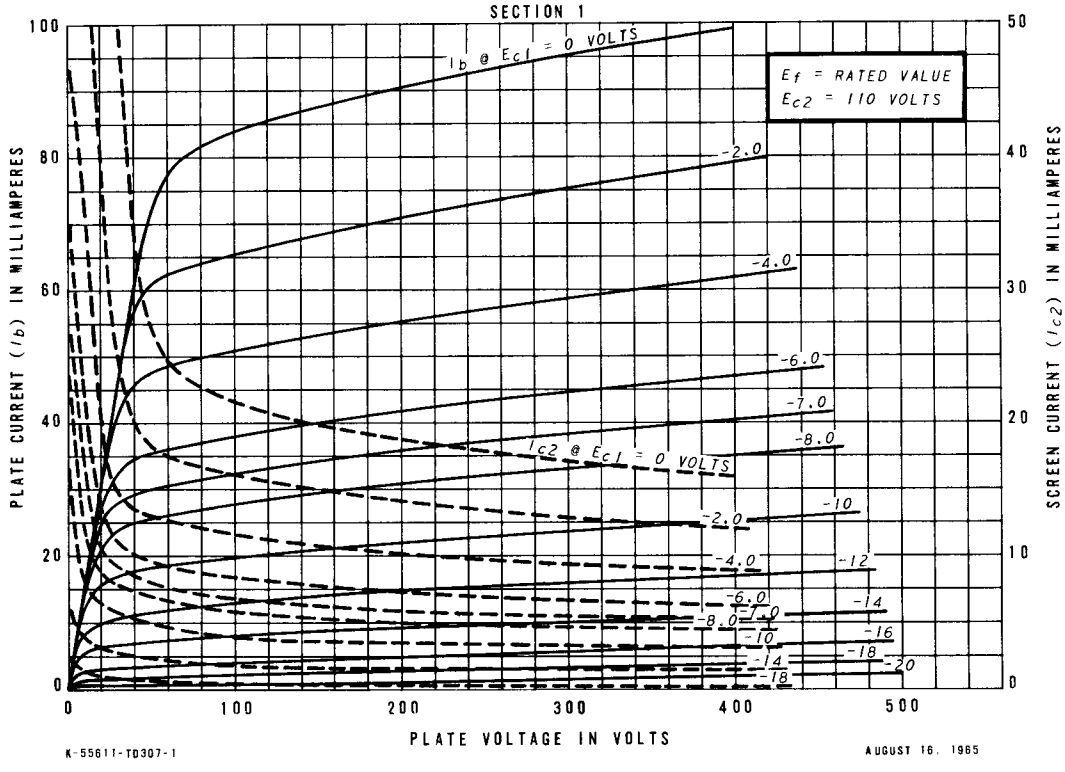
NOTES



* Heater voltage for a bogey tube at If = 0.45 amperes.

‡ The equipment designer should design the equipment so that heater current is centered at the specified bogey value, with heater supply variations restricted to maintain heater current within the specified tolerance.

§ The time required for the voltage across the heater to reach 80 percent of the bogey value after applying 4 times the bogey heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the bogey heater current.

Electronic TUBES

12AE6-A

DUPLEX-DIODE TRIODE

DESCRIPTION AND RATING

The 12AE6-A is a miniature tube containing a medium-mu triode and two diodes. Intended for use as a combined AF voltage amplifier, audio detector, and AVC rectifier in automobile radio receivers, the tube is specially designed to operate with its plate voltage supplied directly from a 12-volt storage battery.

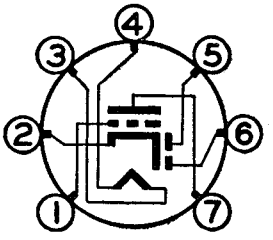
Design-Center ratings are limiting values of operating and environmental conditions applicable to a bogey tube of a specified type as defined by its published data, and should not be exceeded under normal conditions.



These values are chosen by the tube manufacturer to provide acceptable serviceability of the tube in average applications, taking responsibility for normal changes in operating conditions due to rated supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all tubes.

The equipment manufacturer should design so that initially no design-center value for the intended service is exceeded with a bogey tube in equipment operating at the stated normal supply-voltage.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

ALUMINIZED

DESCRIPTION AND RATING

The General Electric Type 12ARP- is a 12-1/2 inch diameter, dual beam, electrostatic focus and deflection cathode ray tube, having minimum pattern distortion, deflection defocusing, and tracking error.

An aluminized screen is used for greater light output and for stabilization of screen potential.

NOTES:

1. The values shown are for each unit unless otherwise stated.

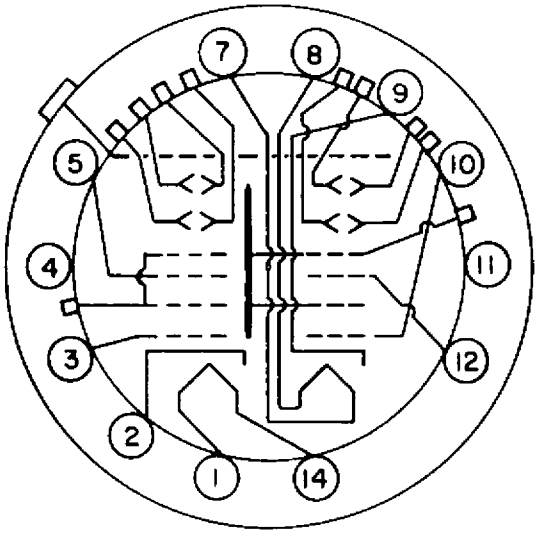
2. The visual extinction of the focused, undeflected spot.

3. For a beam current of 2 μAdc, measured in accordance with MIL-E-1 specifications,

4. The measurement of tracking error shall be made as follows:

   The focused spots of both guns shall be moved by means of a common d-c voltage along the 1D2 axis until the spot of gun A is at +3 inches from the center of the tube. Then by means of a small correction voltage the spot of gun B shall be moved to the same 1D2 position. The spots then shall be moved by means of the common d-c voltage in the opposite direction until the spot of the less sensitive gun reaches -3 inches by means of a voltage divider. The procedure is repeated until 1D2 deflection factor compensation is complete. The entire procedure is then duplicated along the 3D4 axis with a distance from the center of ±3 inches. Then by means of the two common d-c voltages the spots shall be tracked over the area within a circle 10 inches in diameter. If desired, a small correction voltage may be applied to the plates of one gun to allow optimum spot positioning for minimum over-all tracking error.

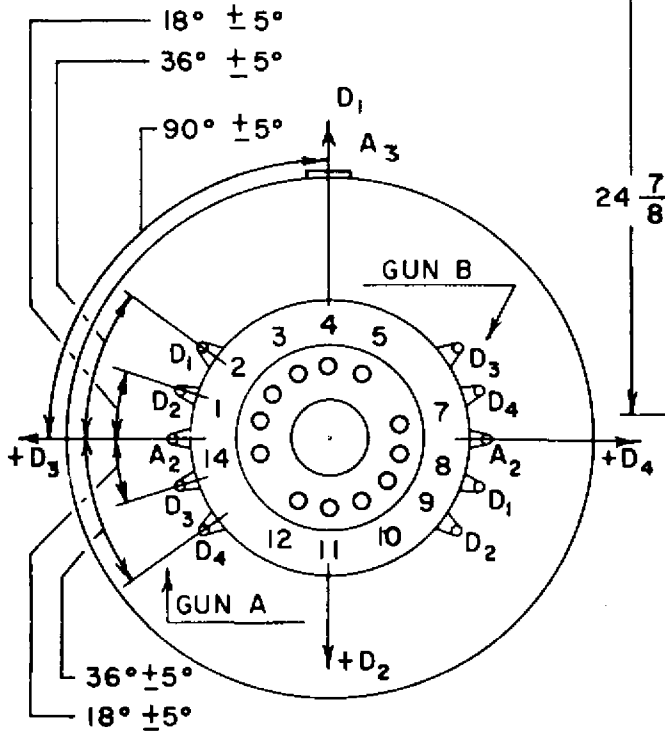
   The separation of spots over the tracking area shall not exceed .15 inches.



5. Deflection per unit volt of one beam at any position of the beam within its useful scan when a balanced voltage of at least plus or minus 300 volts is applied to the 1D2 deflection electrodes of the other electron gun shall be not greater than the value specified herein.

6. Defocusing of the spot resulting from all causes is a minimum within an area 10 inches in diameter. Specifically, the degradation in spot size anywhere within a circle 10 inches in diameter compared to the spot size of compromise focus will not exceed 1.5 to 1.

7. When the tube is operated at typical operating conditions, with Ec1 adjusted to avoid damage to the screen, with each of the deflecting electrodes connected to the accelerator, and with the tube shielded against external influences, the spot will fall within a 5/8-inch radius circle, centered on the tube face.



8. It is recommended that the deflection electrode circuit resistances be approximately equal.

* The maximum ratings provide a ten percent safety factor in accordance with the standard design-center system of rating cathode ray tubes. The tube will withstand the combined effects of variations in line voltage and components provided the maximum design-center values are not exceeded by more than ten percent.

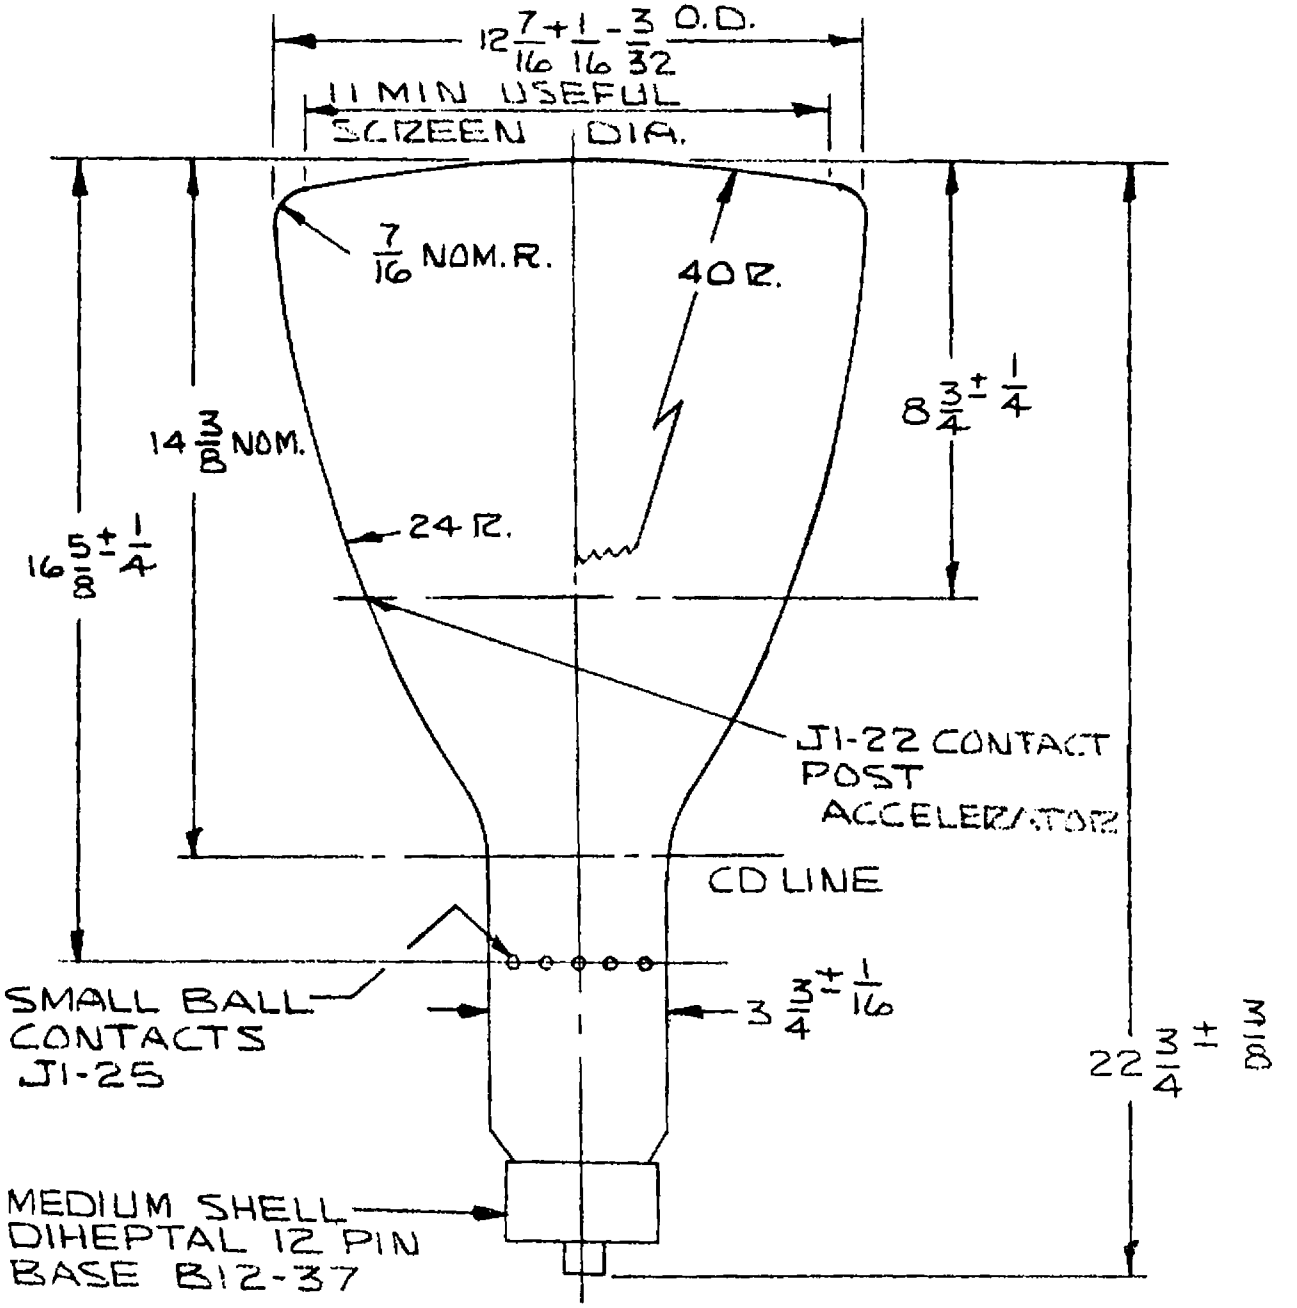
\+ Anode, Grid No. 2 and Grid No. 4 which are connected together within the tube are referred to herein as anode.

++ Anode input equals the product of anode voltage and average current measured at the terminal.

\# For visual extinction of focused undeflected spot.

⫪ For a lb3 of 25 microamperes d-c in accordance with MIL-E-1 specification.

⌀ With post-accelerator anode voltage of 9,700 volts, the center of the focused undeflected spot will lie within a square of 20 millimeters radius centered on the tube face.



△ Measured with specification MIL-E-1, paragraph 4.12.6.1, at an anode No. 3 (post-acceleration) current of 25 microamperes d.c.

◇ It is recommended that the deflection electrode resistance be approximately equal.

12AU7-A—12AU7—7AU7

TWIN TRIODE

DESCRIPTION AND RATING

The 12AU7-A is a miniature medium-mu twin triode intended for service in radio and television receivers or in audio amplifiers. The tube is suitable for use in a variety of stages, such as general-purpose amplifier, phase inverter, oscillator, or multivibrator.

The electrical characteristics of the 12AU7-A and 12AU7 are essentially equivalent. As compared to the 12AU7, the 12AU7-A exhibits a lower microphonic output.

Except for heater ratings, the 7AU7 is identical to the 12AU7-A. In addition, the 7AU7 incorporates a controlled heater warm-up characteristic and is specially suited for use in television receivers that employ 600-milliampere, series-connected heaters.

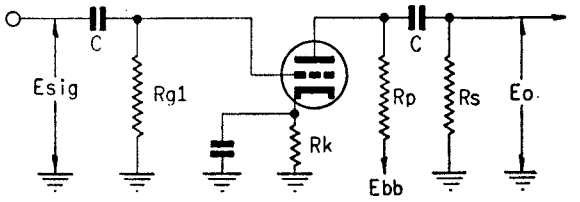
* The time required for the voltage across the heater to reach 80 percent of its rated value after applying 4 times rated heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the rated heater voltage divided by the rated heater current.

† With external shield (RETMA 315) connected to cathode of section under test.

‡ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations", Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.



§ Value given is to be considered as an Absolute Maximum Rating. In this case, the combined effect of supply voltage variation, manufacturing variation including components in the equipment, and adjustment of equipment controls should not cause the rated value to be exceeded.

△In stages operating with grid-lead bias, an adequate cathode-bias resistor or other suitable means is required to protect the tube in the absence of excitation.

Design-Center ratings are limiting values of operating and environmental conditions applicable to a bogey tube of a specified type as defined by its published data, and should not be exceeded under normal conditions.

These values are chosen by the tube manufacturer to provide acceptable serviceability of the tube in average applications, taking responsibility for normal changes in operating conditions due to rated supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all tubes.

The equipment manufacturer should design so that initially no design-center value for the intended service is exceeded with a bogey tube in equipment operating at the stated normal supply-voltage.

12AY7

TWIN TRIODE

FOR LOW-LEVEL AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 12AY7 is a miniature medium-mu twin triode designed primarily for use in low-level stages of high-gain audio-frequency amplifiers. The tube is specially designed to exhibit low noise and low microphonic output. In addition, hiss and hum output voltages are controlled to limits consistent with the requirements of low-level amplifier applications.

GENERAL

ELECTRICAL

MAXIMUM RATINGS

DESIGN-CENTER VALUES, Each Section

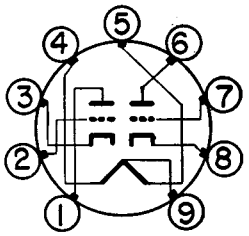

Plate Voltage	300	Volts
Plate Dissipation	1.5	Watts
DC Cathode Current	10	Milliamperes
Heater-Cathode Voltage		
Heater Positive with Respect to Cathode	90	Volts
Heater Negative with Respect to Cathode	90	Volts

Design-Center ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under normal conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube in average applications, making allowance for normal changes in operating conditions due to rated supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially no design-center value for the intended service is exceeded with a bogey tube under normal operating conditions at the stated normal supply voltage.

Electronic TUBES

12B4-A

TRIODE

FOR TV VERTICAL DEFLECTION APPLICATIONS

DESCRIPTION AND RATING

The 12B4-A is a miniature low-mu triode designed primarily for service as a vertical-deflection amplifier in television receivers. The tube features high plate current at relatively low plate voltages and is capable of withstanding the high pulse voltages normally encountered in this application.

In addition, the 12B4-A exhibits a controlled heater warm-up characteristic which makes the tube particularly suited for use in television receivers which employ series-connected heaters. When the 12B4-A is used in conjunction with other 600-milliampere types which exhibit essentially the same heater warm-up characteristic, heater voltage surges across the individual tubes are minimized during the warm-up period.

Except for the controlled heater warm-up time characteristic, the 12B4-A is identical to the 12B4.

12BH7-A

TWIN TRIODE

DESCRIPTION AND RATING

The 12BH7-A is a miniature, medium-mu twin triode designed primarily for use as a vertical-deflection amplifier in television receivers. In this application, the two sections may be employed in parallel, or they may be employed as a combined vertical-deflection amplifier and vertical oscillator. The tube is also suitable for use as the horizontal oscillator in television receivers as well as in a wide variety of general-purpose applications. Each section of the 12BH7-A features a relatively high plate current at low plate voltages and is capable of withstanding the high pulse voltages normally encountered in vertical-amplifier applications.

The 12BH7-A differs from the 12BH7 primarily by incorporating a controlled heater warm-up characteristic which makes the tube particularly suited for use in television receivers which employ 600-milliampere series-connected heaters.

* When used in automotive service from a 12-volt source, under no circumstances should the heater voltage be less than 10.0 volts or more than 15.9 volts. These extreme variations in heater voltage may be tolerated for short periods; however, operation at or near these absolute limits in heater voltage necessarily involves sacrifice in performance at low heater voltage and in life expectancy at high heater voltage. Equipment reliability can be significantly increased with improved supply-voltage regulation.

† With external shield (RETMA 316) connected to pin 7.

Electronic TUBES

12BY7-A

PENTODE

FOR TV VIDEO AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 12BY7-A is a miniature power pentode designed primarily for use as the video output amplifier in television receivers. Features of the tube include extremely high transconductance, low interelectrode capacitances, and high power sensitivity.

Electrically and mechanically, the 12BY7-A is a replacement for the 12BY7. In addition, however, the 12BY7-A exhibits a controlled heater warm-up characteristic which makes the tube particularly suited for use in television receivers which employ series-connected heaters. When the 12BY7-A is used in conjunction with other 600-milliampere types which exhibit essentially the same heater warm-up characteristic, heater voltage surges across the individual tubes are minimized during the warm-up period.

Design-Center ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under normal conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube in average applications, making allowance for normal changes in operating conditions due to rated supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially no design-center value for the intended service is exceeded with a bogey tube under normal operating conditions at the stated normal supply voltage.

NOTES

ϕ Heater voltage for a bogey tube at If = 0.3 amperes.
¶ Heater voltage for a bogey tube at If = 0.45 amperes.
* Heater voltage for a bogey tube at If = 0.6 amperes.
† For series heater operation, the equipment designer should design the equipment so that heater current is centered at the specified bogey value, with heater supply variations restricted to maintain heater current within the specified tolerance.
‡ The time required for the voltage across the heater to reach 80 percent of its rated value after applying 4 times rated heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the rated heater voltage divided by the rated heater current.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

Electronic TUBES

12CT8

TRIODE-PENTODE

DESCRIPTION AND RATING

The 12CT8 is a miniature triode-pentode designed for use in compact, 300-milliampere, series-string television receivers. The pentode section is designed primarily for use as a video amplifier. The triode section is suitable for service as a sync amplifier, separator, or clipper, or as a sweep oscillator.

The 12CT8 has a controlled heater warm-up characteristic as required for use in television receivers that employ series-connected heaters. It also features high performance capabilities at the low d-c supply voltages normally available in these applications.

The 12CT8 is similar to the 6AU8, from which it differs primarily in heater ratings, basing arrangement, length of envelope, and maximum ratings.

Grid-Number 1 Circuit Resistance	12 Megohms

Design-Maximum Ratings are the limiting values expressed with respect to bogie tubes at which satisfactory tube life can be expected to occur for the types of service for which the tube is rated. Therefore, the equipment designer must establish the circuit design so that initially and throughout equipment life no design-maximum value is exceeded with a bogie tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, and environmental conditions.

† When used in automobile service from a 12-volt source, under no circumstances should the heater voltage be less than 10.0 volts or more than 15.9 volts. These extreme variations in heater voltage may be tolerated for short periods; however, operation at or near these absolute limits in heater voltage necessarily involves sacrifice in performance at low heater voltage and in life expectance at high heater voltage. Equipment reliability can be significantly increased with improved supply-voltage regulation.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

NOTES

* Operated with the two sections of the heater connected in parallel and the resulting combination in series with the heaters of other tubes having the same bogey heater current.

‡ Operated with the two sections of the heater connected in parallel and the resulting combination in parallel with the heaters of other tubes having the same bogey heater voltage.

§ Operated with the two sections of the heater connected in series and the resulting combination in parallel with the heaters of other tubes having the same bogey heater voltage.

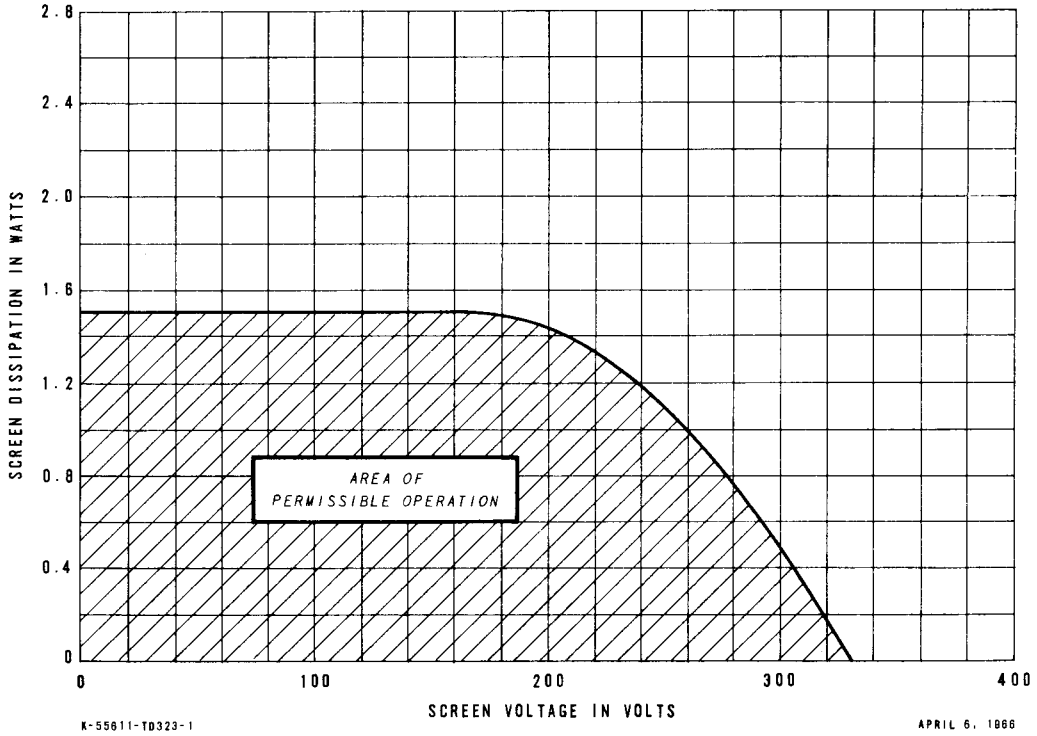
¶ Heater voltage for a bogey tube at If = 0.6 amperes.

\# For parallel heater operation, the equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance; for series heater operation, the equipment designer should design the equipment so that heater current is centered at the specified bogey value, with heater supply variations restricted to maintain heater current within the specified tolerance.

Δ Heater current of a bogey tube at Ef = 6.3 volts.

¢ Heater current of a bogey tube at Ef = 12.6 volts.

** The time required for the voltage across the heater to reach 80 percent of the bogey value after applying 4 times the bogey heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the bogey heater voltage divided by the bogey heater current.



‡‡ Without external shield.

§§ Control grid to cathode spacing of this type is of such low order of magnitude as to preclude the use of voltage between these elements of more than 50 volts dc or peak ac in commercial tube checkers or shorts-indicating devices, particularly where mechanical excitation of the tube is employed.

¶¶ Applied for a short interval (two seconds maximum) so as not to damage tube.

MAXIMUM CIRCUIT VALUES

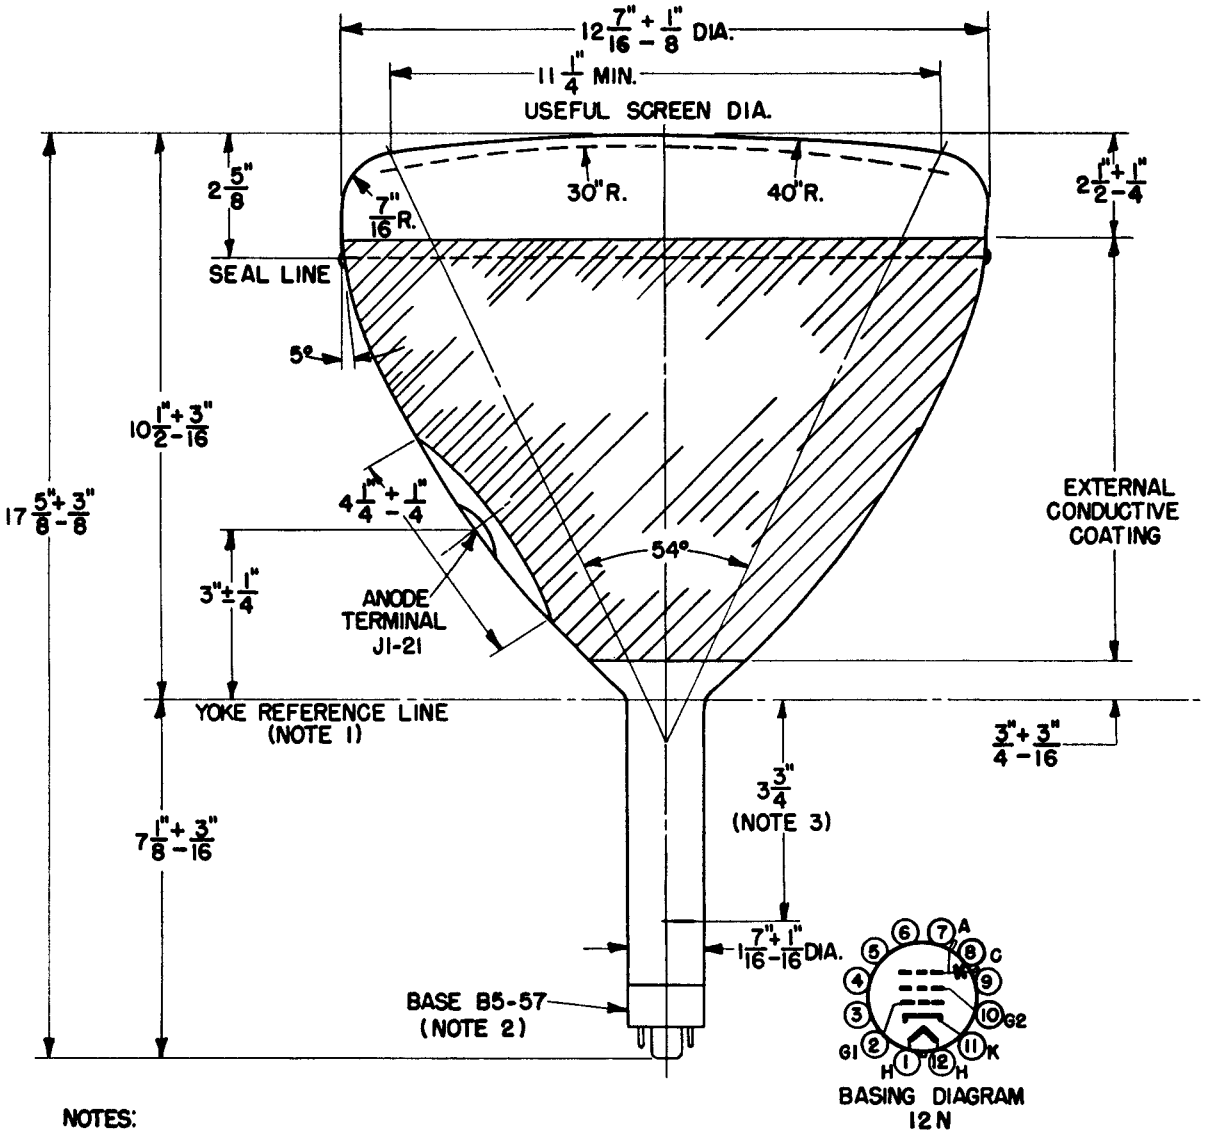
Grid-No. 1 Circuit Resistance	1.5 Max	Megohms

* The maximum ratings provide a ten-percent safety factor in accordance with the standard design-center system of rating cathode-ray tubes. The tube will withstand the combined effects of variations in line voltage and components provided the maximum design-center values are not exceeded by more than ten percent.


† Anode and grid-No. 3 which are connected together within the tube are referred to herein as anode.
‡ Cathode should be returned to one side or to the midtap of the heater transformer winding.

§ Brightness and focus quality decrease with decreasing anode voltage. In general, the anode voltage should not be less than 8000 volts.
π For visual extinction of focused raster.
▲For JETEC focusing coil No. 106 with distance from the yoke-reference-line to center-of-air-gap equal to 4½ inches.
♦ Double-field ion-trap magnet adjusted to optimum position, equivalent to 120 miliamperes through JETEC ion-trap magnet No. 108.

NOTES:
1. REFERENCE LINE IS DETERMINED BY THE PLANE OF THE UPPER EDGE OF THE REFERENCE-LINE GAGE (RETMA NO. 112) WHEN THE GAGE IS RESTING ON THE CONE.
2. ANODE TERMINAL ALIGNS WITH PIN-NO. 3 POSITION ± 30 DEGREES.
3. APPROXIMATE POSITION OF ION-TRAP MAGNET.
4. RECOMMENDED POSITION FOR CENTER OF FOCUSING FIELD.

Electronic TUBES

12R5

PENTODE

FOR TV VERTICAL-DEFLECTION AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 12R5 is a miniature beam pentode primarily designed for use as a pentode-connected vertical-deflection amplifier in television receivers. The tube features high zero-bias plate current at relatively low plate and screen voltages. In addition, a controlled heater warm-up characteristic makes it especially suited for use in television receivers with series-connected heaters.

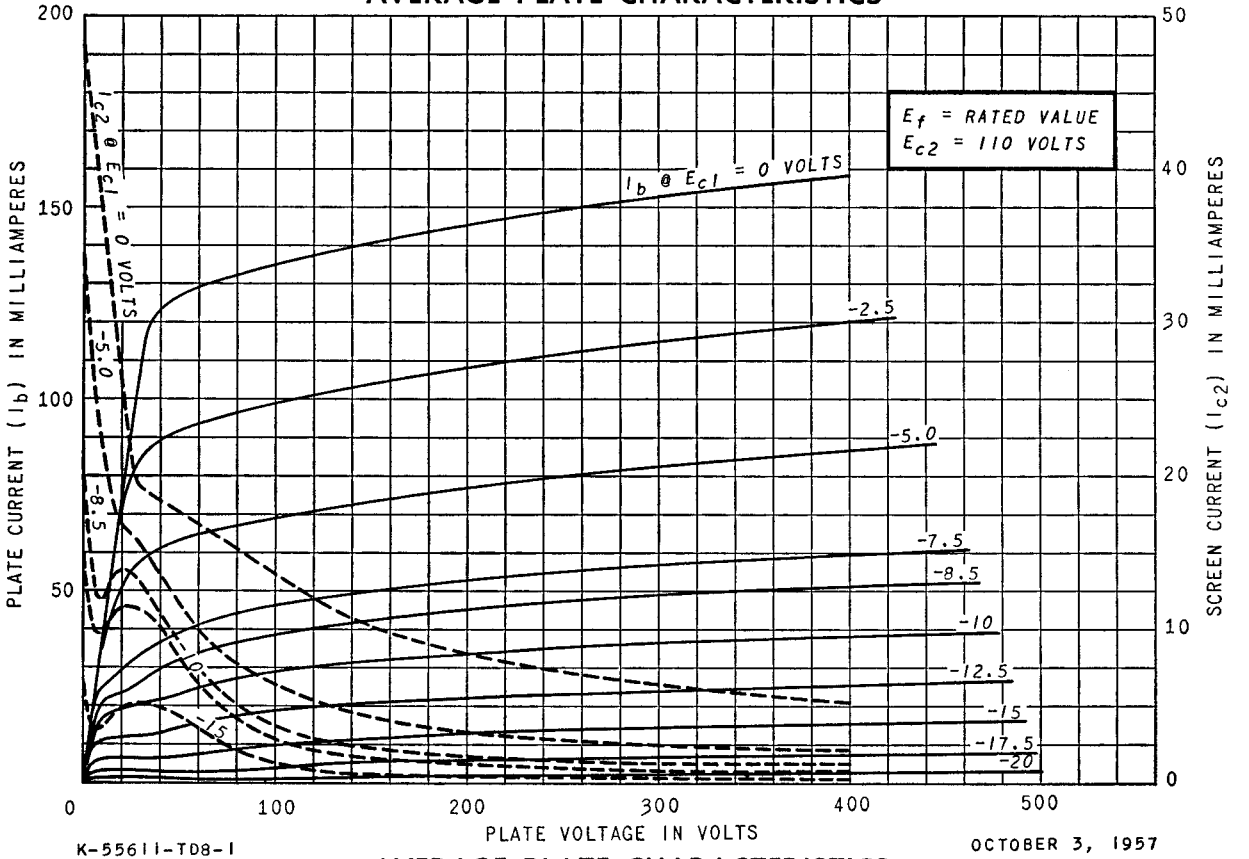
* The time required for the voltage across the heater to reach 80 percent of its rated value after applying 4 times rated heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the rated heater voltage divided by the rated heater current.

† Without external shield.



‡ For operation in 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

§ Value given is to be considered as an Absolute Maximum Rating. In this case, the combined effect of supply voltage variation, manufacturing variation including components in the equipment, and adjustment of equipment controls should not cause the rated value to be exceeded.

△In stages operating with grid-leak bias, an adequate cathode bias-resistor or other suitable means is required to protect the tube in the absence of excitation.

¶ Applied for short interval (2 seconds maximum) so as not to damage tube.

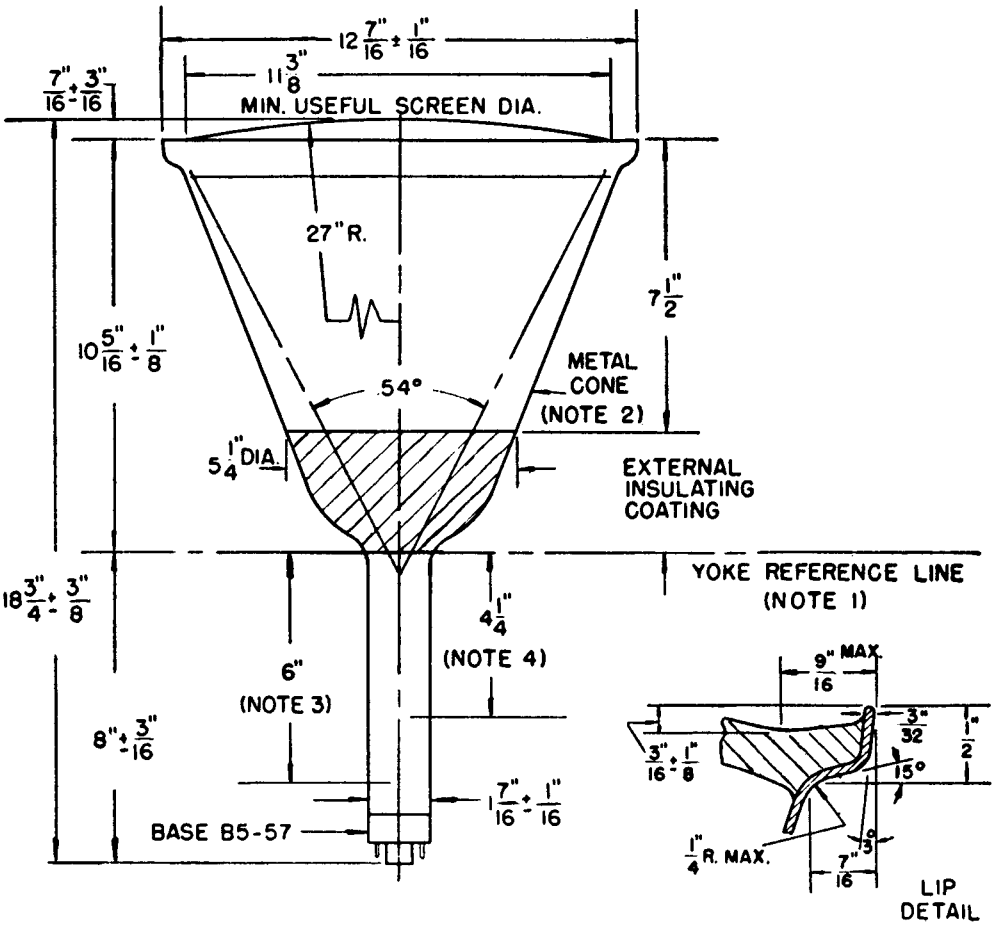
♦ All voltages are measured with respect to cathode.

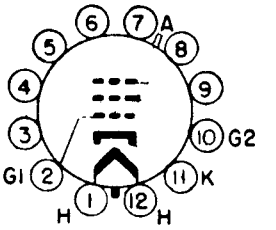
* The maximum ratings provide a ten-percent safety factor in accordance with the standard design-center system of rating cathode-ray tubes. The tube will withstand the combined effects of variations in line voltage and components provided the maximum design-center values are not exceeded by more than ten percent.



† Anode and grid-No. 3 which are connected together within the tube are referred to herein as anode.

‡ Brightness and focus quality decrease with decreasing anode voltage. In general, the anode voltage should not be less than 9000 volts.

§ For visual extinction of focused raster.



π For RETMA focusing coil No. 109 with distance from the yoke-reference-line to center-of-air-gap equal to 4¼ inches.

△Single-field ion-trap magnet adjusted to optimum position, equivalent to 33 milliamperes through RETMA ion-trap magnet No. 117.

NOTES

1. REFERENCE LINE IS DETERMINED BY THE PLANE OF THE UPPER EDGE OF THE REFERENCE-LINE GAGE (RETMA NO 112) WHEN THE GAGE IS RESTING ON THE CONE.
2. METAL CONE OPERATES AT HIGH VOLTAGE AND MUST BE INSULATED TO WITHSTAND THE MAXIMUM APPLIED ANODE VOLTAGE.
3. APPROXIMATE POSITION OF ION-TRAP MAGNET.
4. RECOMMENDED POSITION FOR CENTER OF FOCUSING FIELD.

DESCRIPTION AND RATING

12W6-GT Beam Pentode. Identical to the 6W6-GT except for heater ratings and heater-cathode voltage ratings and addition of a controlled heater-warm-up characteristic. Refer to the 6W6-GT Description and Rating sheet for complete data.

12X4 Twin Diode. Identical to the 6X4 except for the following ratings:

Heater Voltage, AC or DC	12.6 ±10%	Volts
Heater Current	0.3	Amperes

When used in automotive service from a 12-volt battery source, the permissible range in heater voltage is from 10.0 to 15.9 volts. Refer to the 6X4 Description and Rating sheet for complete data.

Dissimilar Double Triode

13GF7-A

FOR TV VERTICAL-DEFLECTION OSCILLATOR AND AMPLIFIER APPLICATIONS

The 13GF7-A is a dissimilar double triode designed for use as a combined vertical-deflection oscillator and amplifier in television receivers. Section one, a high-mu triode, is intended for service as an oscillator; section two, a low-mu, high-perveance triode, for service as an amplifier. The 13GF7-A utilizes a T-9 bulb and features a 9-pin glass button base with a 0.687-inch circle.

Except for heater characteristics and ratings, the 13GF7-A is identical to the 6GF7-A.

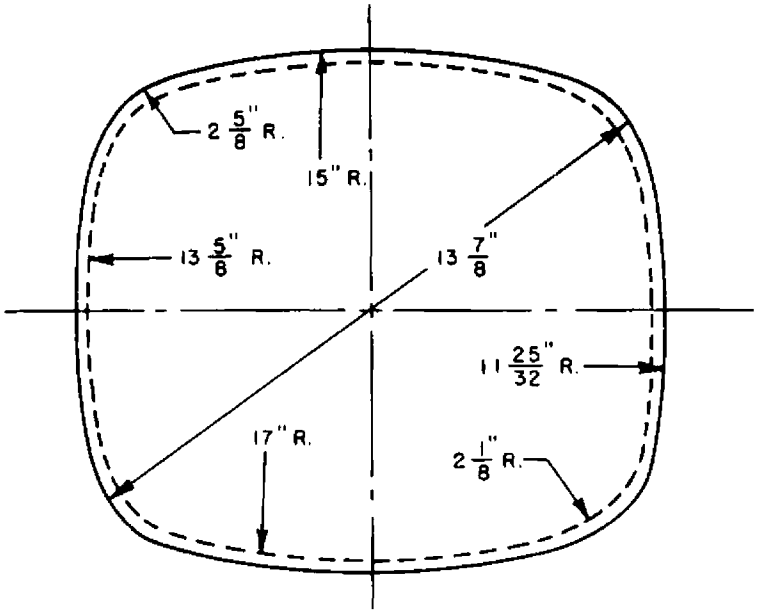
MAXIMUM CIRCUIT VALUES

Grid-No. 1 Circuit Resistance	1.5 Max	Megohms

* Heater warm-up time is the time required for the voltage across the heater terminals to increase to 5.0 volts in the JETEC test circuit, with E = 25 volts and series R = 42 ohms.

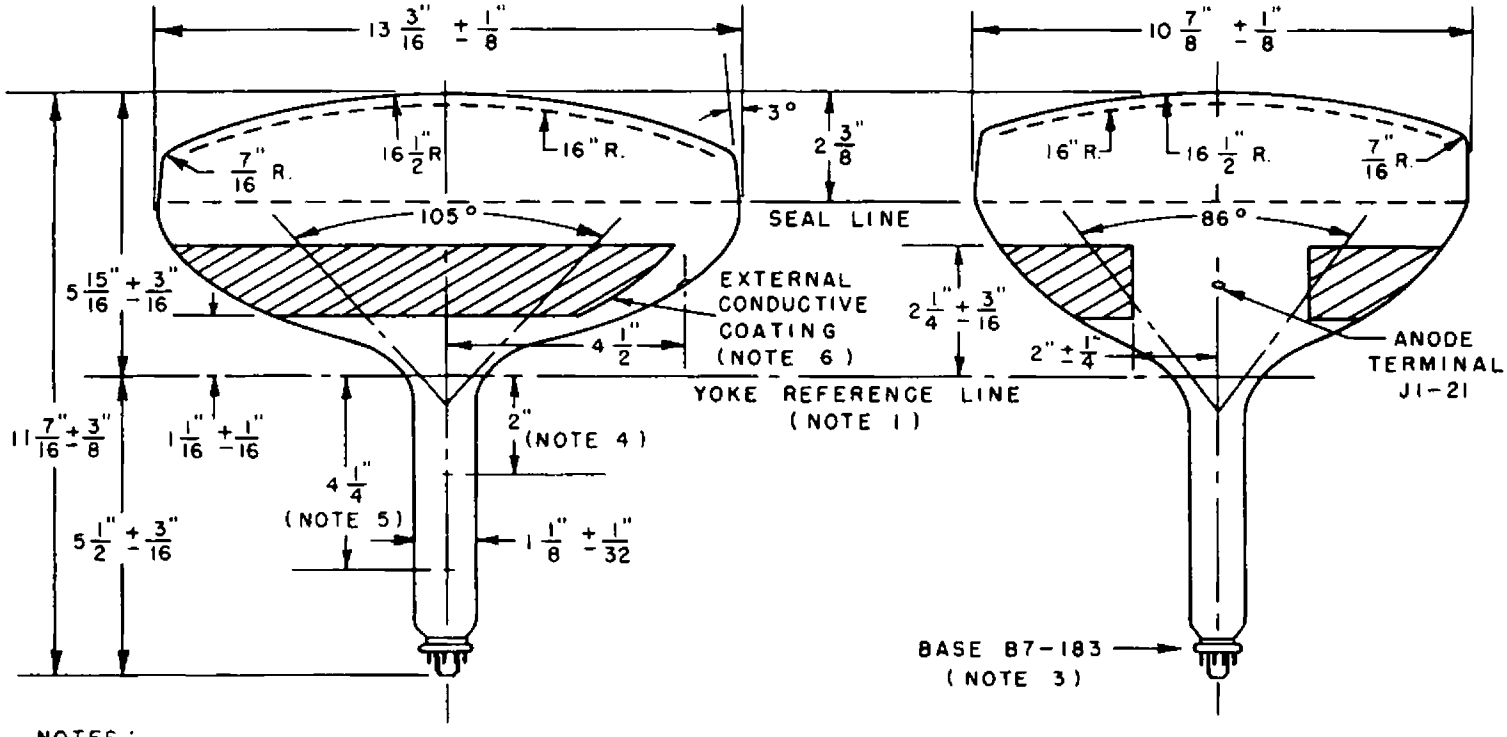
/ The maximum ratings provide a ten-percent safety factor in accordance with the standard design-center system of rating cathode-ray tubes. The tube will withstand the combined effects of variations in line voltage and components provided the maximum design-center values are not exceeded by more than ten percent.



\# Anode, grid-No. 3, and grid-No. 5 which are connected together within the tube are referred to herein as anode.

** Brightness and focus quality decrease with decreasing anode voltage. In general, the anode voltage should not be less than 8,000 volts.

$\neq$ For visual extinction of focused raster.



\#\# For a Heppner PM ion-trap magnet or equivalent located in optimum position and rotated to give maximum brightness.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

NOTES

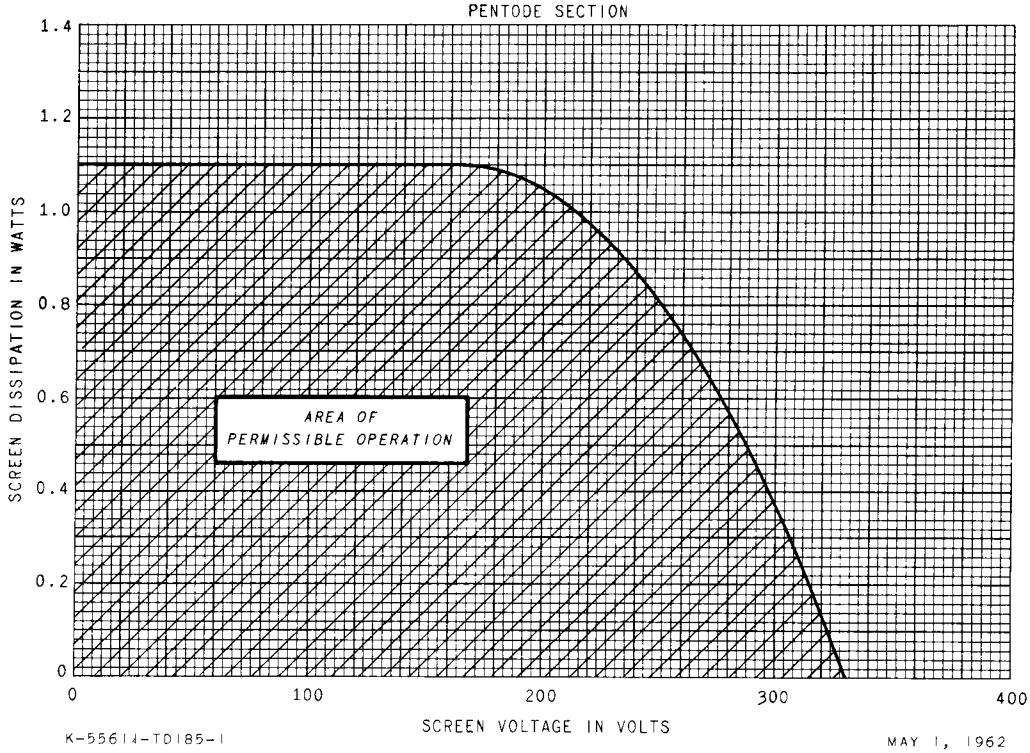
★ Heater voltage for a bogey tube at If = 0.45 amperes.



● The equipment designer should design the equipment so that heater current is centered at the specified bogey value, with heater supply variations restricted to maintain heater current within the specified tolerance.

♦ The time required for the voltage across the heater to reach 80 percent of the bogey value after applying 4 times the bogey heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the bogey heater voltage divided by the bogey heater current.

▲ Without external shield.

EXTERNAL CONDUCTIVE COATING

DESCRIPTION AND RATING

The 14CP4 is a magnetic-focus and deflection, direct-view all-glass picture tube which provides a 11⅜- by 8½-inch picture for television applications. The electron gun is used with an external single-field ion-trap magnet. Other features of this tube include a high-quality gray faceplate which increases picture contrast and detail under high-ambient-light conditions, and a space-saving rectangular face shape. An external conductive coating serves as a filter capacitor when grounded.

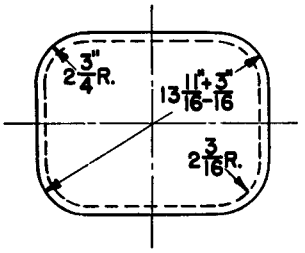
* The maximum ratings provide a ten-percent safety factor in accordance with the standard design-center system of rating cathode-ray tubes. The tube will withstand the combined effects of variations in line voltage and components provided the maximum design-center values are not exceeded by more than ten percent.

† Anode and grid-No. 3 which are connected together within the tube are referred to herein as anode.

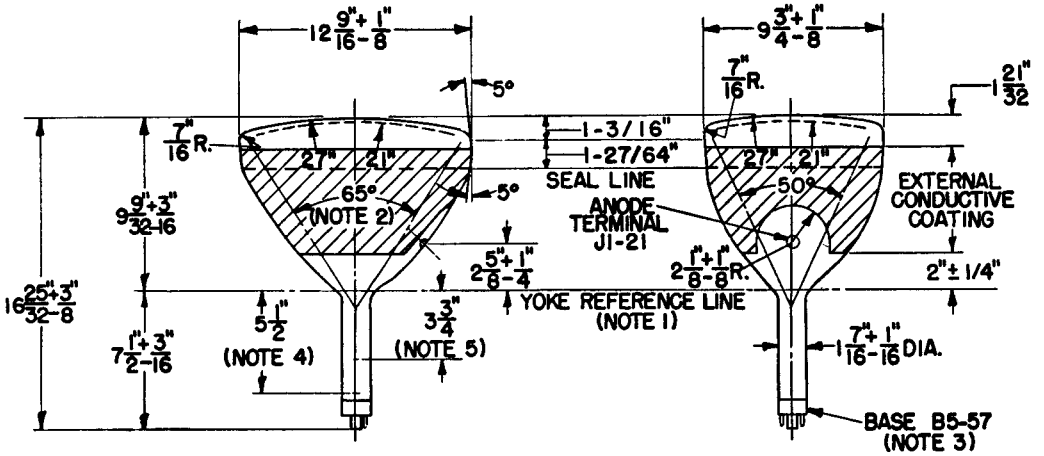
If this tube is operated at voltages in excess of 16,000 volts, x-ray radiation shielding may be necessary to avert possible danger of personal injury from prolonged exposure at close range. The protective face-viewing window of apparatus using tubes of this type may provide such a safeguard. If the radiation measured in contact with this window does not exceed 6.25 milliroentgens per hour, the window will normally provide adequate protection.



‡ Cathode should be returned to one side or to the midtap of the heater transformer winding.

§ Brightness and focus quality decrease with decreasing anode voltage. In general, the anode voltage should not be less than 10,000 volts.

π For visual extinction of focused raster.



▲ For JETEC focusing coil No. 109 with distance from the yoke-reference-line to center-of-air-gap equal to 3¾ inches.

♦ Single-field ion-trap magnet adjusted to optimum position, equivalent to 32 milliamperes through JETEC ion-trap magnet No. 117.

DESCRIPTION AND RATING

The 14QP4-A is a 14-inch rectangular all-glass picture tube which provides an 11⅜- by 8½-inch picture for direct-view television applications. It employs electrostatic focusing and magnetic deflection. Features of this tube include a short neck for cabinet economy, a fluorescent screen which is aluminized to increase light output, a high-quality gray faceplate to increase picture contrast, and an external conductive coating which serves as a filter capacitor when grounded.

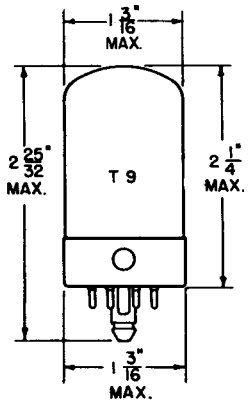
Description and Rating

DUPLEX-DIODE PENTODE

GENERAL DESCRIPTION



Principal Application: The 14R7 is a duplex diode, semi-remote-cutoff pentode suitable for use as a combined detector, automatic-volume-control rectifier and audio amplifier. The pentode section may also be used as a radio-frequency or intermediate-frequency amplifier. The tube features low coupling capacitance between the diode units and the pentode section.

DESCRIPTION AND RATING

The 14UP4 is a 14-inch rectangular picture tube employing magnetic focusing and deflection. It has a high-resolution electron gun which provides a small round spot with considerable depth of focus. Other features include a high-quality fluorescent screen which is aluminized to increase light output, and a gray faceplate to improve picture contrast.

DESCRIPTION AND RATING

THREE-GUN TRI-COLOR PICTURE TUBE

11 1/2 by 8 5/8-INCH PICTURE SIZE

15-INCH ROUND, GLASS	FACEPLATE - SPHERICAL, CLEAR
FOCUS - ELECTROSTATIC	CONVERGENCE - ELECTROSTATIC
DEFLECTION - MAGNETIC	EXTERNAL CONDUCTIVE COATING
45-DEGREE DEFLECTION ANGLE	METAL-BACKED PHOSPHOR-DOT SCREEN

The 15GP22 is a direct-view tri-color picture tube capable of reproducing either full-color or black-and-white transmissions. It has three separate electron guns and a phosphor-dot screen on which are deposited small dots of blue, green and red phosphor arranged in triangular groups. There are approximately 195,000 such groups or a total of 585,000 dots. A perforated mask between the guns and the screen permits the beam from any one gun to strike phosphor dots of only one color. Thus, the three guns produce independent pictures, in the three different colors, which appear to be superimposed because of the close spacing of the dots. Proper registration of the three pictures is achieved through electrostatic convergence of the beams. The screen provides an 11 1/2 by 8 5/8-inch picture with rounded sides and has a metal backing to prevent ion-spot blemish and to increase light output. An external conductive coating serves as a filter capacitor when grounded.

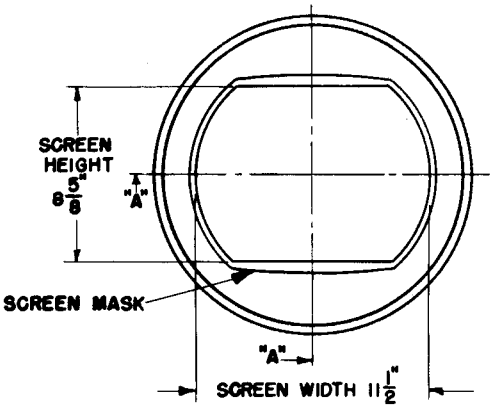
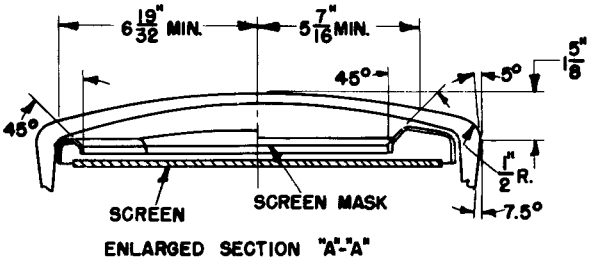
◊ The maximum ratings provide a ten-percent safety factor in accordance with the standard design-center system of rating cathode-ray tubes; that is, the tube will withstand the combined effects of variations in line voltage and components provided the maximum design-center values are not exceeded by more than ten percent.

† The aquadag coating, aperture mask, and metal screen-backing, which are connected together within the tube, are referred to herein as the anode.

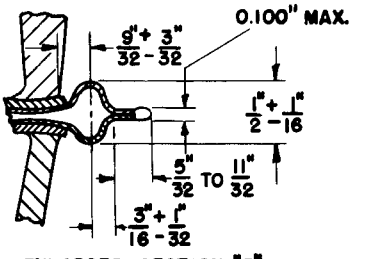


If this tube is operated at voltages in excess of 16,000 volts, x-ray radiation shielding may be necessary to avert possible danger of personal injury from prolonged exposure at close range. The protective face-viewing window of apparatus using tubes of this type may provide such a safeguard. If the radiation measured in contact with this window does not exceed 6.25 milliroentgens per hour, the window will normally provide adequate protection.



Δ Anode input equals the product of anode voltage and anode current, the latter being measured at the anode contact with a direct-current ammeter.

§ Does not include the d-c component of the dynamic coverging voltage.



‡ Centering of the raster on the screen is accomplished by passing direct current of the required value through each pair of deflecting coils to compensate for the raster shift resulting from optimum adjustments for convergence, color purity, and concentricity.

π Peak to peak value. This a-c voltage, essentially parabolic in wave-form, is synchronized with scanning and does not include any voltage developed during the blanking time.

DESCRIPTION AND RATING

The 16ATP4 is a 16 inch electrostatic-focus and magnetic deflection glass lightweight picture tube employing an integral plastic implosion barrier. Other outstanding features include a short over-all length, a small neck diameter and a non ion trap gun designed for operation at a low Grid No. 2 voltage for use in cathode-drive circuits. The fluorescent screen is aluminized to increase light output and reduce undesirable screen charging. An external conductive coating is provided to serve as a filter capacitor when grounded.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

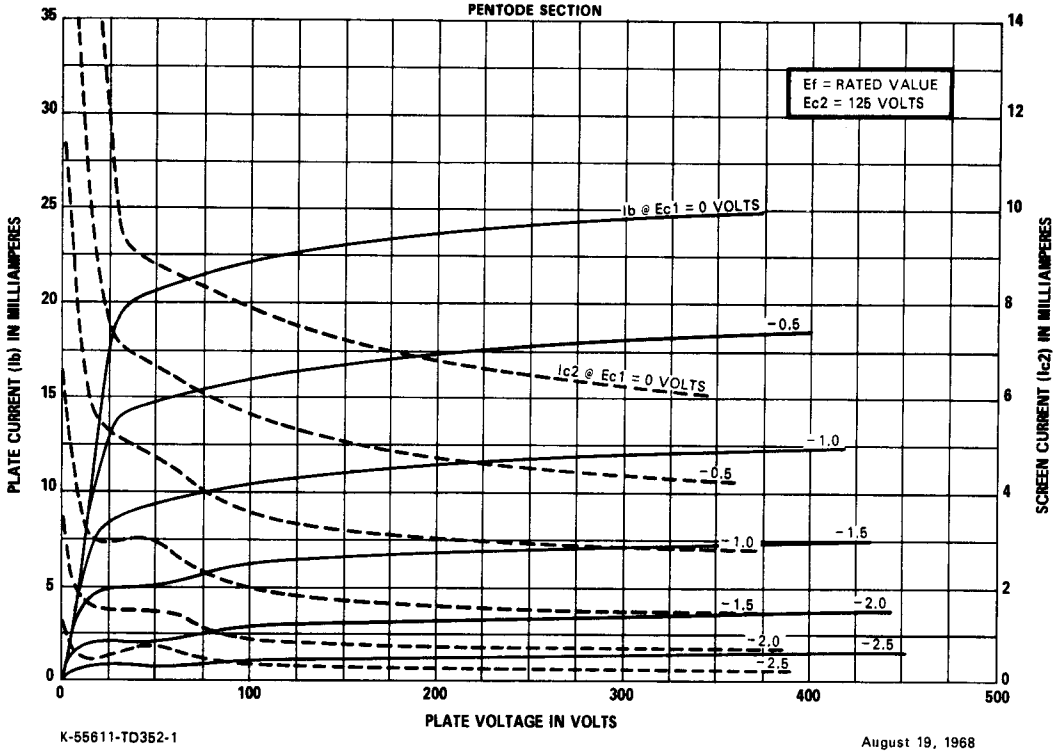
NOTES



★ Heater voltage for a bogey tube at If = 0.315 amperes.

● The equipment designer should design the equipment so that heater current is centered at the specified bogey value, with heater supply variations restricted to maintain heater within the specified tolerance.

♦ The time required for the voltage across the heater to reach 80 percent of the bogey value after applying 4 times the bogey heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the bogey heater voltage divided by the bogey heater current.

▲ Without external shield.

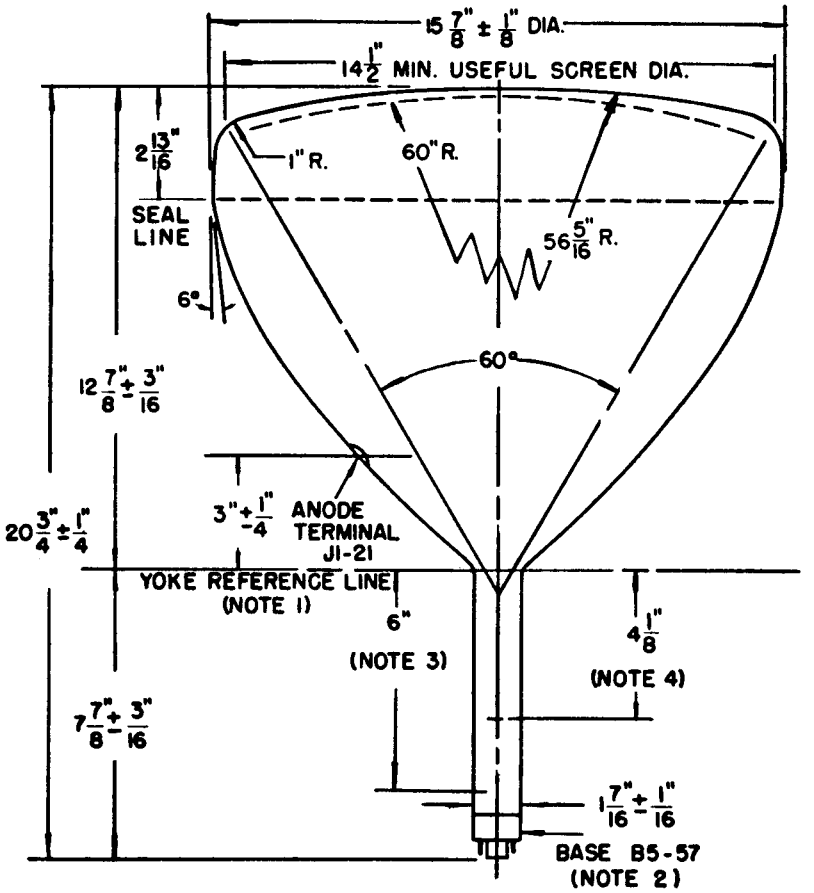
♦ All voltages are measured with respect to cathode.

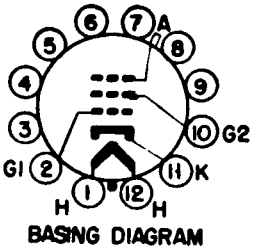
* The maximum ratings provide a ten-percent safety factor in accordance with the standard design-center system of rating cathode-ray tubes. The tube will withstand the combined effects of variations in line voltage and components provided the maximum design-center values are not exceeded by more than ten percent.



† Anode and grid-No. 3 which are connected together within the tube are referred to herein as anode.

‡ Brightness and focus quality decrease with decreasing anode voltage. In general, the anode voltage should not be less than 9,000 volts.

§ For visual extinction of focused raster.



π For RETMA focusing coil No. 109 with distance from the yoke-reference-line to center-of-air-gap equal to 4⅛ inches.

△Double-field ion-trap magnet adjusted to optimum position, equivalent to 120 milliamperes through RETMA ion-trap magnet No. 108.

NOTES:

1. REFERENCE LINE IS DETERMINED BY THE PLANE OF THE UPPER EDGE OF THE REFERENCE-LINE GAGE (RETMA NO. 112) WHEN THE GAGE IS RESTING ON THE CONE.
2. ANODE TERMINAL ALIGNS WITH PIN-NO. 3 POSITION ±30 DEGREES.

DESCRIPTION AND RATING

The 16KP4-A/16RP4-A is a magnetic-focus and deflection direct-view all-glass picture tube which provides a 13½- by 10⅛-inch picture for television applications. The electron gun is designed for use with an external single-field ion-trap magnet. Other features of this tube include a high-quality gray faceplate which increases picture contrast and detail under high ambient light conditions, and a space-saving rectangular face shape. An external conductive coating serves as a filter capacitor when grounded.

The tube also features a reflective aluminized screen which increases light output.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

DESCRIPTION AND RATING

The 17AVP4-A is a rectangular all-glass picture tube employing electrostatic-focus and magnetic-deflection. It provides a 14¼ by 10¾-inch picture for direct-view television applications. The electron gun has a focusing-voltage range of −0.4 to +2.2 percent of the anode voltage and is designed for use with an external single-field ion-trap magnet. Other features of the 17AVP4-A include a high-quality fluorescent screen which is aluminized to increase light output, a gray faceplate to improve picture contrast, a 90-degree deflection angle and a short neck design both of which provide a short over-all tube length, and an external conductive coating which serves as a filter capacitor when grounded.

TELEVISION PICTURE TUBE

DESCRIPTION

The 17BP4-B is a magnetic-focus and -deflection, direct-view picture tube for television applications. It provides a $10\frac{3}{4}$ by $14\frac{1}{4}$-inch picture. Features of this tube include a high-quality, neutral-density faceplate which increases picture contrast and detail under high ambient light conditions, and a reflective, metal-backed screen which improves brightness. Other features are an electron gun designed to be used with an external ion-trap magnet and a space-saving rectangular face shape. An external conductive coating serves as a filter capacitor when grounded.

Electronic TUBES

17H3

DIODE

FOR TV DAMPING DIODE APPLICATIONS

DESCRIPTION AND RATING

The 17H3 is a miniature heater-cathode type diode intended for service as the damping diode in the horizontal-deflection circuit of compact, 300-milliampere series-string television receivers. The tube features relatively small size and low power requirements. It also has a controlled heater warm-up characteristic as required for use in television receivers that employ series-connected heaters.

Design-Maximum Ratings are the limiting values expressed with respect to bogie tubes at which satisfactory tube life can be expected to occur for the types of service for which the tube is rated. Therefore, the equipment designer must establish the circuit design so that initially and throughout equipment life no design-maximum value is exceeded with a bogie tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, and environmental conditions.

DESCRIPTION AND RATING

The 17HP4-B is an electrostatic-focus and magnetic-deflection, direct-view all-glass picture tube which provides a 14¼- by 10¾-inch picture for television applications. The electron gun has a focusing voltage range of −0.4 to +2.2 percent of the anode voltage and is designed for use with an external single-field ion-trap magnet. Other features of this tube include a high-quality gray faceplate which increases picture contrast and detail under high-ambient-light conditions, a reflective aluminized screen to increase light output, and a space-saving rectangular face shape. An external conductive coating serves as a filter capacitor when grounded.

Electronic TUBES

18A5

BEAM PENTODE

DESCRIPTION AND RATING

The 18A5 is a beam-power pentode designed for use as the horizontal-deflection amplifier in compact, 300-milliampere, series-string television receivers. The tube features relatively small size, low power requirements, and high performance capabilities at the low d-c supply voltages normally available in this application. The tube also has a controlled heater warm-up characteristic as required for use in television receivers that employ series-connected heaters.

Design-Maximum Ratings are the limiting values expressed with respect to bogie tubes at which satisfactory tube life can be expected to occur for the types of service for which the tube is rated. Therefore, the equipment designer must establish the circuit design so that initially and throughout equipment life no design-maximum value is exceeded with a bogie tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, and environmental conditions.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

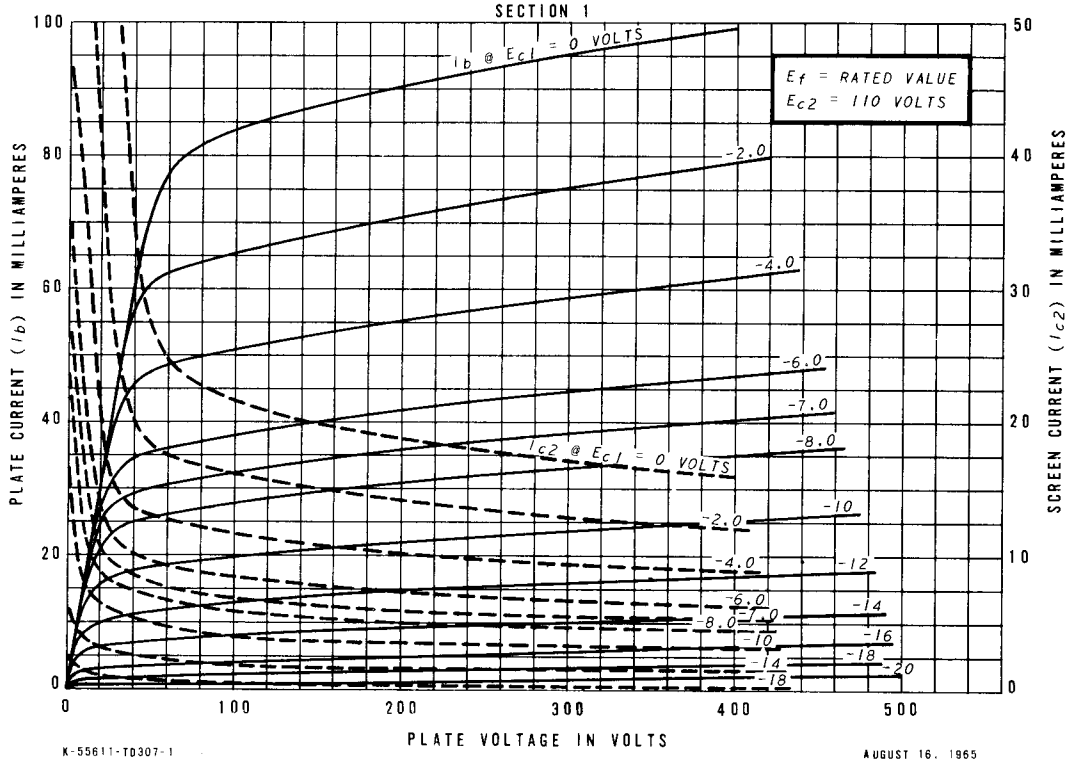
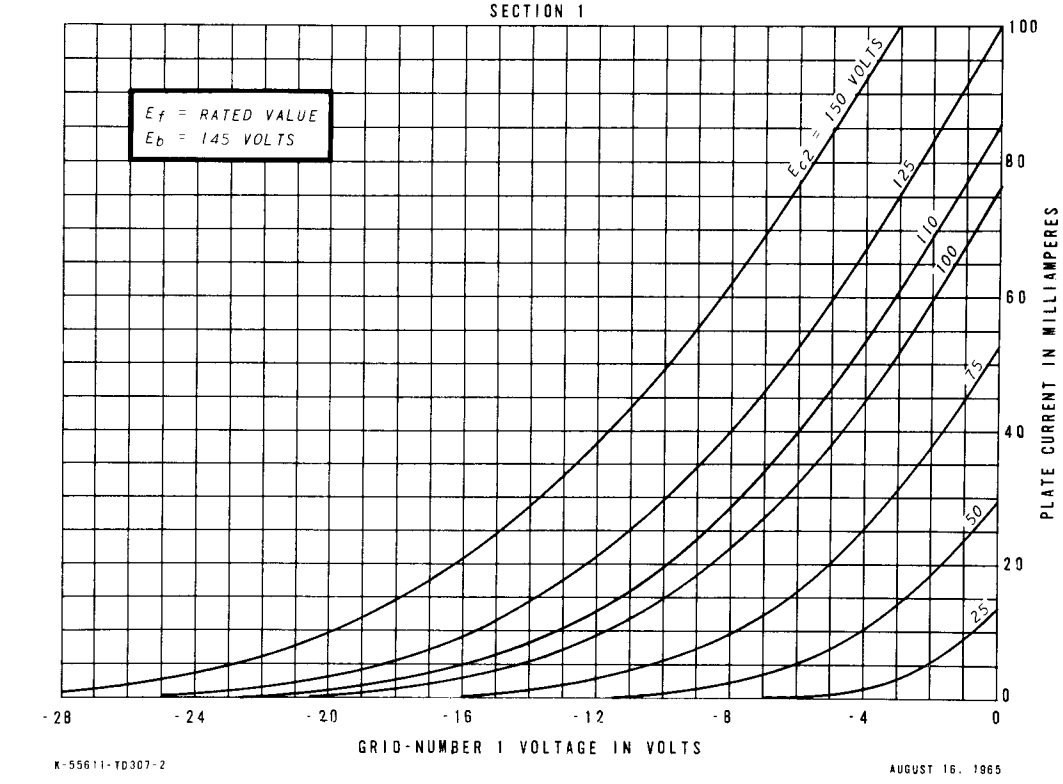
NOTES



* Heater voltage for a bogey tube at If = 0.315 amperes.

† The equipment designer should design the equipment so that heater current is centered at the specified bogey value, with heater supply variations restricted to maintain heater current within the specified tolerance.



‡ The time required for the voltage across the heater to reach 80 percent of the bogey value after applying 4 times the bogey heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the bogey heater voltage divided by the bogey heater current.

§ Without external shield.

DESCRIPTION AND RATING

The 19AP4-A is a magnetic-focus and -deflection direct-view picture tube which provides a 17⅜ by 13-inch picture for television applications. Features of this tube include a lightweight metal cone envelope, a high-quality gray faceplate to increase picture contrast and detail under high ambient light conditions, and an electron gun which is designed for use with an external single-field ion-trap magnet.

The 19AP4-B has the additional feature of a frosted faceplate to prevent specular reflection.

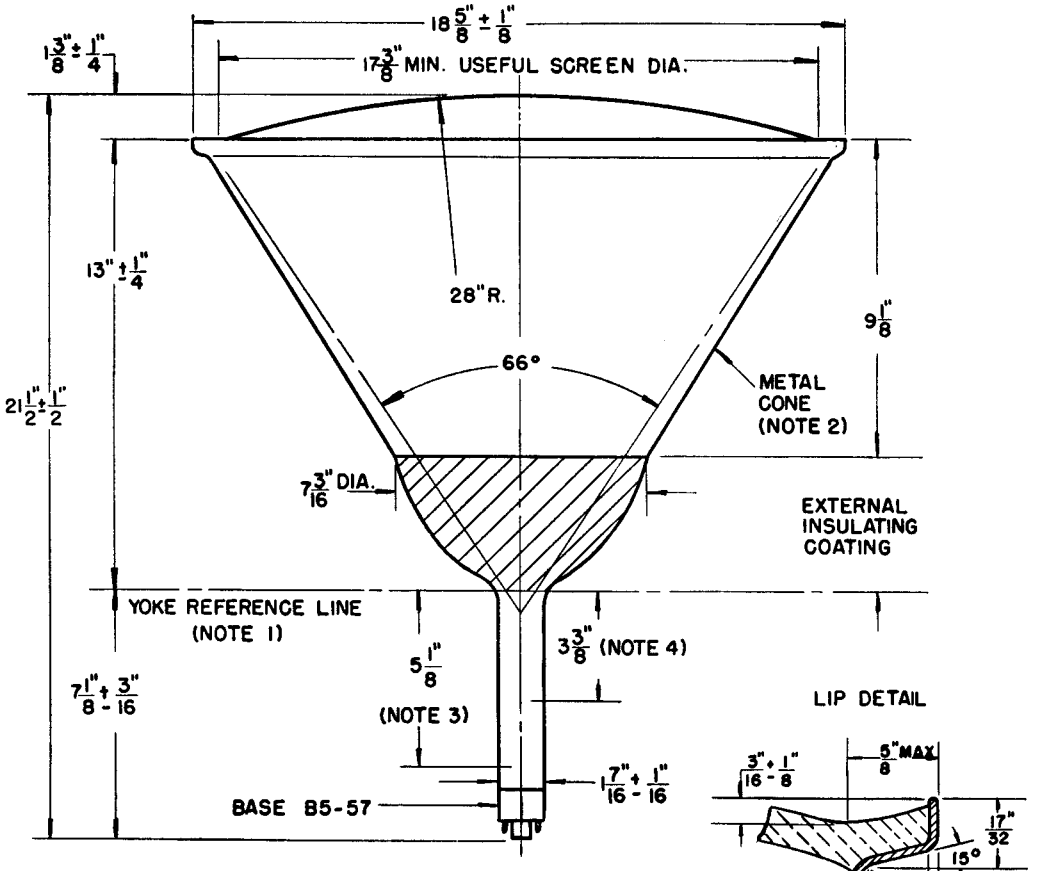
CIRCUIT VALUES

Grid-No. 1 Circuit Resistance	1.5	Max Megohms

♦ All voltages are measured with respect to cathode.

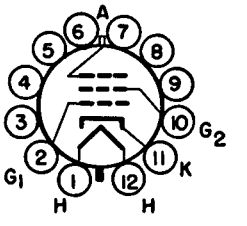
* The maximum ratings provide a ten-percent safety factor in accordance with the standard design-center system of rating cathode-ray tubes. The tube will withstand the combined effects of variations in line voltage and components provided the maximum design-center values are not exceeded by more than ten percent.



† Anode and grid-No. 3 which are connected together within the tube are referred to herein as anode.

‡ Brightness and focus quality decrease with decreasing anode voltage. In general, the anode voltage should not be less than 12,000 volts.

§ For visual extinction of focused raster.



π For RETMA focusing coil No. 109 with distance from the yoke-reference-line to center-of-air-gap equal to 3⅜-inches.

△Single-field ion-trap magnet adjusted to optimum position, equivalent to 37 milliamperes through RETMA ion-trap magnet No. 117.

NOTES:

1. REFERENCE LINE IS DETERMINED BY THE PLANE OF THE UPPER EDGE OF THE REFERENCE-LINE GAGE (RETMA NO. 112) WHEN THE GAGE IS RESTING ON THE CONE.
2. METAL CONE OPERATES AT HIGH VOLTAGE AND MUST BE INSULATED TO WITHSTAND THE MAXIMUM APPLIED ANODE VOLTAGE.
3. APPROXIMATE POSITION OF ION-TRAP MAGNET.
4. RECOMMENDED POSITION FOR CENTER OF FOCUSING FIELD.

DESCRIPTION AND RATING

The 19CKP4 is a 19 inch electrostatic-focus and magnetic deflection glass picture tube. Outstanding features include a short over-all length, a small neck diameter and a non ion trap gun designed for operation at a low Grid No. 2 voltage for use in cathode-drive circuits. The fluorescent screen is aluminized to increase light output and reduce undesirable screen charging. An external conductive coating is provided to serve as a filter capacitor when grounded.

Compactron Diode

19DE3

FOR TV DAMPING DIODE APPLICATIONS

- COLOR TV TYPE
- LOW TUBE DROP
- DIFFUSION BONDED CATHODE
- 5000 VOLTS DC
- 350 MILLIAMPERES DC

The 19DE3 is a compactron containing a single heater-cathode type diode. It is intended for service as the damping diode in the horizontal deflection circuit of color television receivers.

The diffusion bonded cathode practically eliminates one of the major failure mechanisms in damping diodes, which is plate-to-cathode arcing caused by emissive particles being pulled from the cathode by the high electrostatic field.

MAXIMUM RATINGS (Cont'd)

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

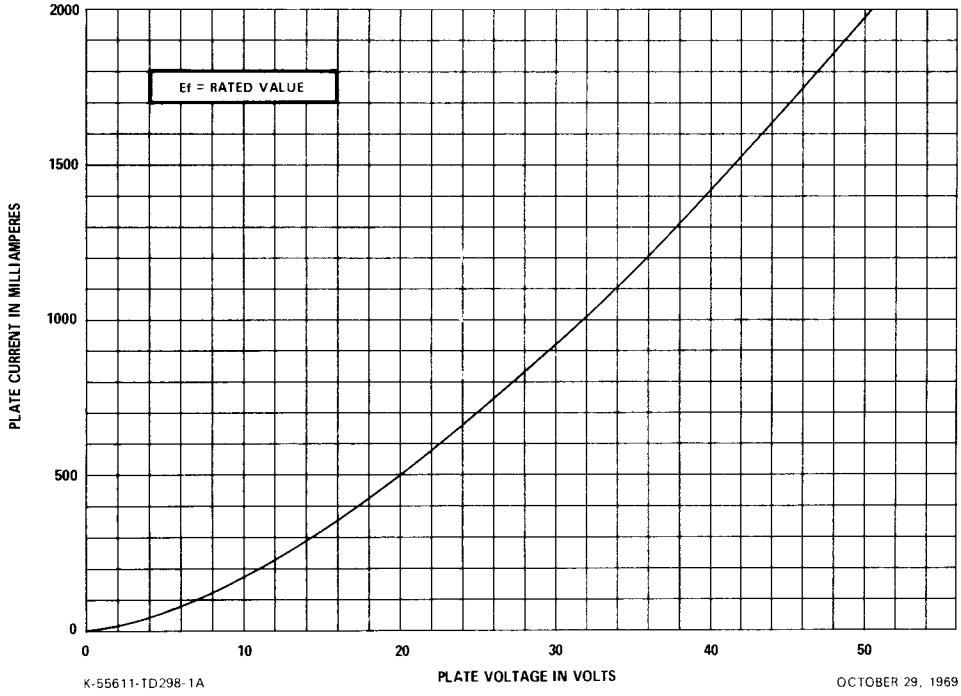
The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

AVERAGE CHARACTERISTICS

Tube Voltage Drop, approximate
Ib = 700 Milliamperes DC.....25 Volts

NOTES

★ Heater voltage for a bogey tube at If = 0.6 amperes.



■ The equipment designer should design the equipment so that heater current is centered at the specified bogey value, with heater supply variations restricted to maintain heater current within the specified tolerance.

♦ The time required for the voltage across the heater to reach 80 percent of the bogey value after applying 4 times the bogey heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the bogey heater voltage divided by the bogey heater current.

▲ Without external shield.

□ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations", Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

With Cathode Bias	2.2	2.2	Megohms

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

19T8

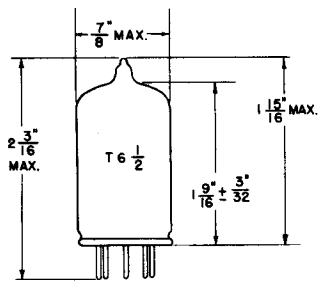
Description and Rating

TRIPLE-DIODE TRIODE

PRELIMINARY DATA

GENERAL DESCRIPTION

Principal Application: The 19T8 is a miniature tube containing three high-perveance diodes and a high-mu triode in the same envelope. One of the diodes has a separate cathode connection.



Cathode:	Coated Unipotential
Heater Voltage (A-C or D-C)	18.9 Volts
Heater Current	0.15 Ampere
Envelope:	T-6½ Glass
Base:	E9-1 Small Glass Button 9-Pin
Mounting Position:	Any

The tube is designed for use as a combined AM and FM detector and audio-frequency amplifier. Except for heater rating, the 19T8 and the 6T8 are identical.

Direct Interelectrode Capacitances:*

Triode Grid to Plate	2.4	μμf
Triode Input	1.5	μμf
Triode Output	1.1	μμf
Grid to Each Diode Plate (Max)	0.03	μμf

DESCRIPTION AND RATING

The 19ZP4 is a 19 inch electrostatic-focus and magnetic deflection glass picture tube. Outstanding features include a short over-all length, a small neck diameter and a non ion trap gun. The fluorescent screen is aluminized to increase light output and reduce undesirable screen charging. An external conductive coating is provided to serve as a filter capacitor when grounded.

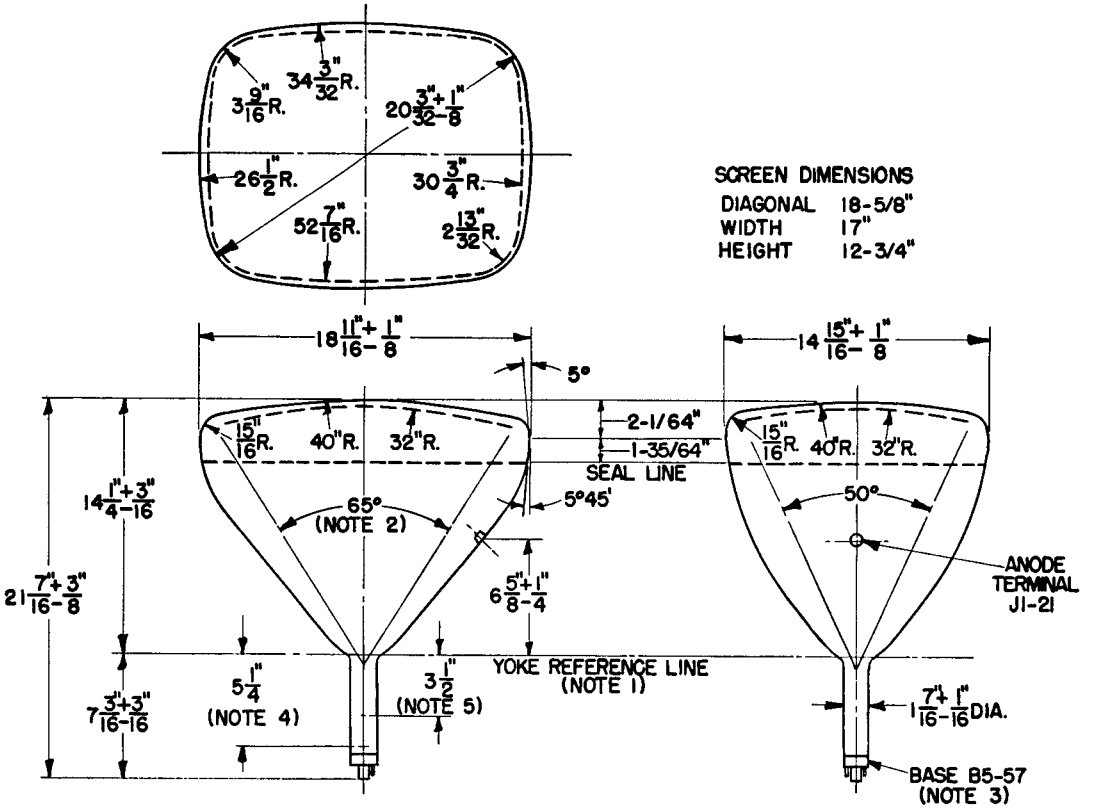
* The maximum ratings provide a ten-percent safety factor in accordance with the standard design-center system of rating cathode-ray tubes. The tube will withstand the combined effects of variations in line voltages and components provided the maximum design-center values are not exceeded by more than ten percent.

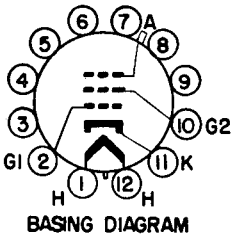
† Anode and grid-No. 3 which are connected together within the tube are referred to herein as anode. If this tube is operated at voltages in excess of 16,000 volts, x-ray radiation shielding may be necessary to avert possible danger of personal injury from prolonged exposure at close range. The protective face-viewing window of apparatus using tubes of this type may provide such a safeguard. If the radiation measured in contact with this window does not exceed 6.25 milliroentgens per hour, the window will normally provide adequate protection.



‡ Cathode should be returned to one side or to the midtap of the heater transformer winding.

§ Brightness and focus quality decrease with decreasing anode voltage. In general, the anode voltage should not be less than 14,000 volts.

π For visual extinction of focused raster.



▲ For JETEC focusing coil No. 109 with distance from the yoke-reference-line to center-of-air-gap equal to 3½ inches.

♦ Single-field ion-trap magnet adjusted to optimum position, equivalent to 40 milliamperes through JETEC ion-trap magnet No. 117.

* The maximum ratings provide a ten-percent safety factor in accordance with the standard design-center system of rating cathode-ray tubes. The tube will withstand the combined effects of variations in line voltage and components provided the maximum design-center values are not exceeded by more than ten percent.

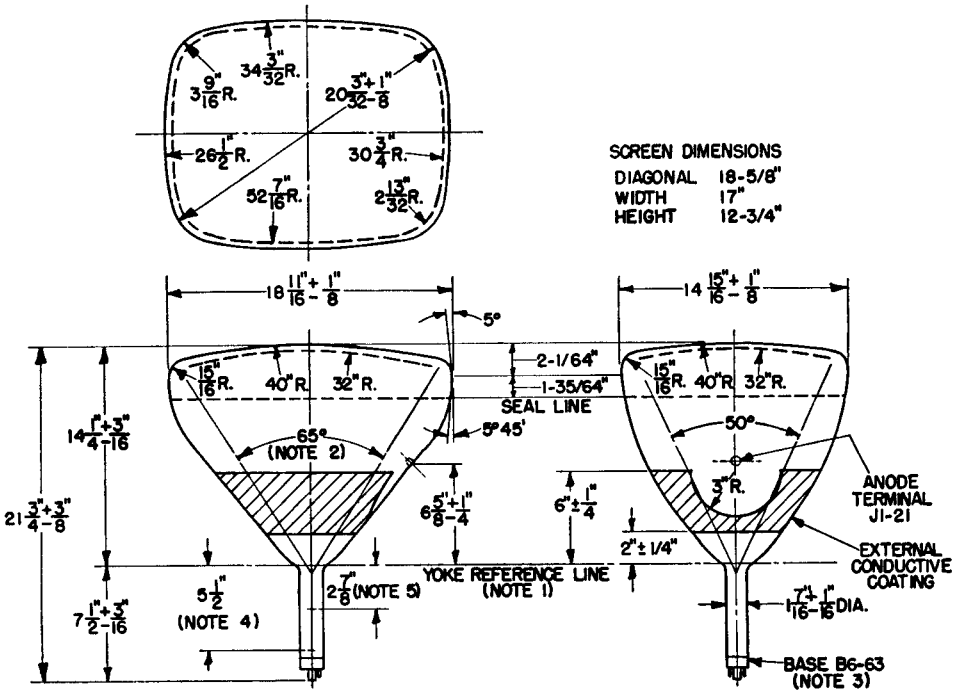
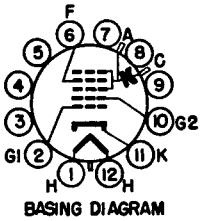
† Anode, grid-No. 3 and grid-No. 5 which are connected together within the tube are referred to herein as anode. If this tube is operated at voltages in excess of 16,000 volts, x-ray radiation shielding may be necessary to avert possible danger of personal injury from prolonged exposure at close range. The protective face-viewing window of apparatus using tubes of this type may provide such a safeguard. If the radiation measured in contact with this window does not exceed 6.25 milliroentgens per hour, the window will normally provide adequate protection.



§ Cathode should be returned to one side or to the midtap of the heater transformer winding.

π Brightness and focus quality decrease with decreasing anode voltage. In general, the anode voltage should not be less than 12,000 volts.

▲ The focusing electrode may be modulated within the stipulated maximum range without damage to the tube.



♦ For visual extinction of focused raster.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

CHARACTERISTICS AND TYPICAL OPERATION

Plate Voltage	160	50	volts
Grid No. 1 Voltage	0	−10	volts
Grid No. 3 Voltage	0	0	volts
Screen Voltage	160	175	volts
Plate Current	1400	800	Milliamperes

OPERATING CONDITIONS

Stabilized Circuits (D.C. Feedback)

Cut-Off Voltage

The minimum required cut-off voltage (−Ec1) during flyback at Eb=7000 volts and Zc1=1 kΩ at line frequency is:

Ec2 = 150 V: Ec1 = −175 V
Ec2 = 175 V: Ec1 = −185 V
Ec2 = 200 V: Ec1 = −195 V
Ec2 = 250 V: Ec1 = −215 V

OPERATING CONDITIONS (Cont'd)

Supply Voltage: Refer to Figures 2, 3 and 4

Minimum Required Plate Voltage (Eb min)

Barkenhausen interference and loss of stability can be prevented by ensuring the plate voltage is above the specified minimum Eb, during the scanning period.

If low values of Eb min. are required, the Eb min. 1–line can be shifted over 10 volts to Eb min. 2 provided a D.C. voltage of at least $\pm$ 20 volts is applied to the beam plate (G3). To compensate for the influence of line voltage variations, the specified values of Eb min. have to be increased with 10% of the plate supply voltage.

Minimum Required Values of the Screen Grid Voltage (Ec2 min.)

The graph refers to nominal line voltage. The specified values of peak plate current will be available throughout life of the tube at supply voltages 10% below nominal.

Maximum Permissible Screen Grid Series Resistance Rc2 max. see Figures 2, 3 and 4

Rc2: To optimize the high tension properties of the tube, it is recommended to apply an unbypassed resistor of 100 ohms at the screen grid of the tube

Rc3: Application of an undecoupled srries resistance of 1000 ohms is recommended.

At Zc1 =200 kΩ (f=50 Hz), Vk/h=220 VRMS and without wiring and socket capacitances the equivalent grid hum voltage is less than 5 mV.

NOTES

- • Maximum pulse duration is 22% of a cycle, but maximum 18 microseconds.
- ♦ Total continuous or accumulated time not to exceed 40 seconds.
- ▲ To prevent an excessive value of Pc2 the minimum Rc2 values are given in Figure 1.
- ⊕ D.C. component maximum 100 volts.
- † With Rc3>10 000 ohms, capacitance decoupling of C3 is not required.
- ⋆ Absolute maximum value.
- ‡ The circuit design has to be such that negative control grid currents up to 5 microamperes do not have detri – mental effect upon tube adjustment or circuit performance. Care should be taken, that with 5 micro–amperes grid current the limiting values for Ik, Pp and Pc2 are not ex–ceeded.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

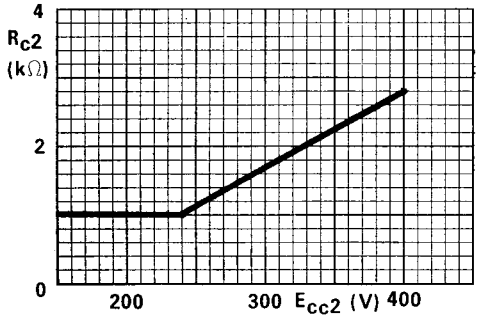

Figure 1

Minimum required plate voltage.
Rc2 maximum: maximum permissible screen grid series resistance for 400 V screen grid supply. The specified values of Ib peak are available at supply voltage 10% below nominal and throughout the tube life.
Note: Rc2 minimum for 400 V screen grid supply is 2.9 kΩ (see Figure 1).

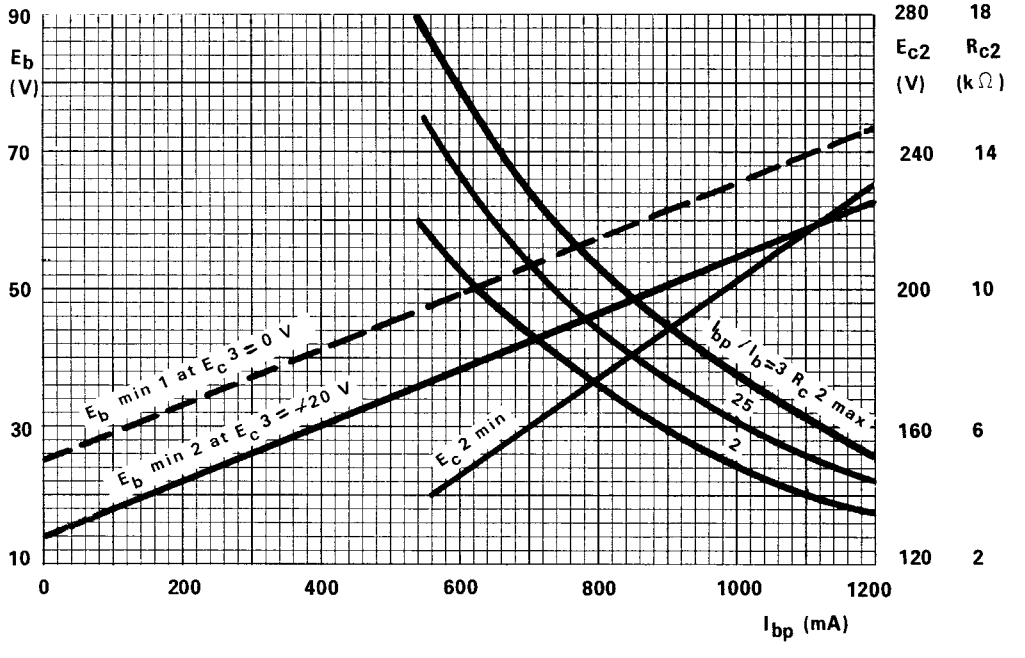

Figure 2

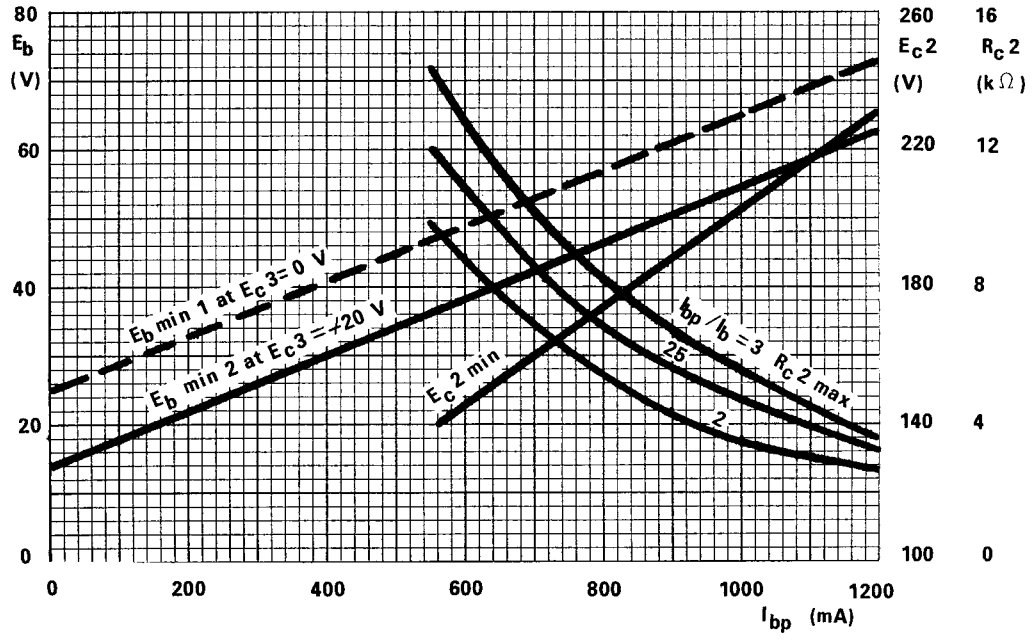

Minimum required plate voltage.

R_c 2 maximum: maximum permissible screen grid series resistance for 350 V screen grid supply.

19⅛ BY 15-INCH PICTURE SIZE
FACEPLATE—SPHERICAL, GRAY
EXTERNAL CONDUCTIVE COATING
ION-TRAP GUN
21ACP4-A—ALUMINIZED SCREEN

DESCRIPTION AND RATING

The 21ACP4 is a magnetic-focus and magnetic-deflection, direct-view all-glass picture tube which provides a 19⅛ by 15-inch picture for television applications. It has an electron gun which is used with an external single-field ion-trap magnet. The ninety-degree deflection angle allows a reduction in tube length and an increase of approximately 4.5 percent in screen area over tubes with narrower angles. Other features of this tube include a high-quality gray faceplate which increases picture contrast and detail under high ambient light conditions, and a space-saving rectangular face shape. An external conductive coating serves as a filter capacitor when grounded.

The 21ACP4-A has the additional feature of a reflective aluminized screen which increases light output.

DESCRIPTION AND RATING

CATHODE-RAY TUBE 21ARP4

19-1/8 by 14-3/16-INCH PICTURE SIZE

21-INCH RECTANGULAR, GLASS	FACEPLATE — SPHERICAL, GRAY
BUILT-IN FOCUSING UNIT	BUILT-IN ION-TRAP MAGNET
DEFLECTION — MAGNETIC	EXTERNAL CONDUCTIVE COATING
70-DEGREE DEFLECTION ANGLE	OPERATING RANGE — 14 to 18 KILOVOLTS

The 21ARP4 is a magnetic-focus and magnetic-deflection, direct-view all-glass picture tube which provides a 19-1/8 by 14-3/16-inch picture for television applications. In this tube, an ion-trap magnet and a magnetic focusing unit are integral parts of the electron gun. The ion-trap magnet assures proper alignment of the electron beam and eliminates the adjustable external magnet usually required. The focusing unit permits a sharp over-all focus adjustable through a wide range of anode voltage by a magnetic shunt sleeve around the tube neck. Other features of this tube include a high-quality gray faceplate which increases picture contrast and detail under high ambient light conditions, and a space-saving rectangular face shape. An external conductive coating serves as a filter capacitor when grounded.

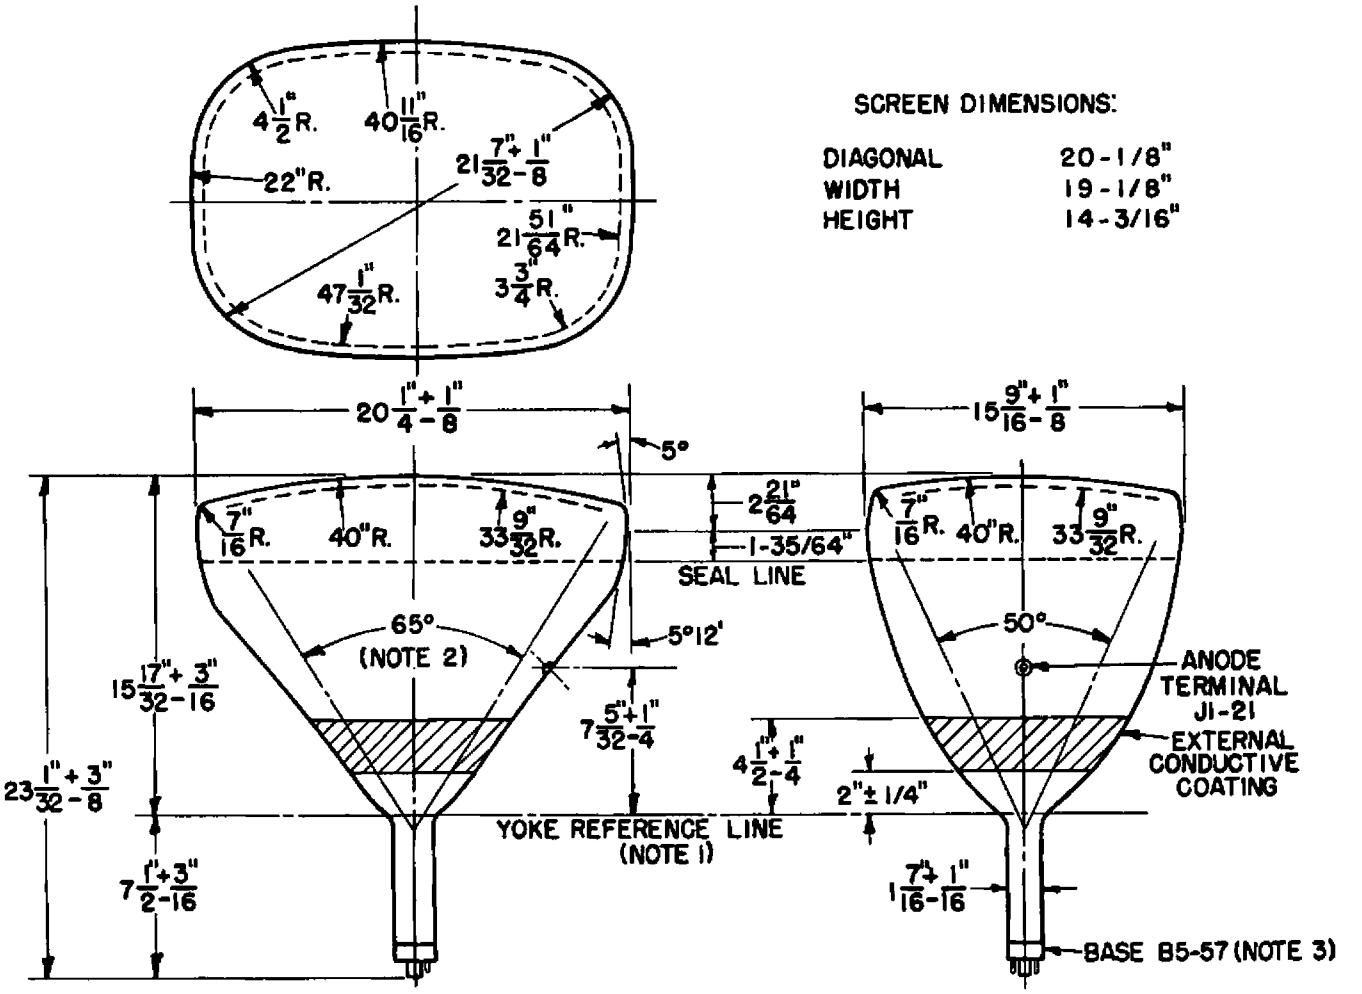
* The maximum ratings provide a ten-percent safety factor in accordance with the standard design-center system of rating cathode-ray tubes. The tube will withstand the combined effects of variations in line voltages and components provided the maximum design-center values are not exceeded by more than ten percent.

† Anode and grid-No. 3 which are connected together within the tube are referred to herein as anode.



If this tube is operated at voltages in excess of 16,000 volts, x-ray radiation shielding may be necessary to avert possible danger of personal injury from prolonged exposure at close range. The protective face-viewing window of apparatus using tubes of this type may provide such a safeguard. If the radiation measured in contact with this window does not exceed 6.25 milliroentgens per hour, the window will normally provide adequate protection.

‡ Anode input equals the product of anode voltage and anode current, the latter being measured at the anode contact with a direct-current ammeter.

§ Cathode should be returned to one side or to the midtap of the heater transformer winding.

Δ Optimum focusing conditions require that the tube be operated within the specified voltage range. The tube, however, will safely withstand the rated maximum anode voltage.

π For visual extinction of focused raster.

BUILT-IN FOCUSING UNIT	METAL-BACKED SCREEN
DEFLECTION - MAGNETIC	EXTERNAL CONDUCTIVE COATING
70-DEGREE DEFLECTION ANGLE	OPERATING RANGE - 13 to 19 KILOVOLTS

The 21ARP4-A is a magnetic-focus and magnetic-deflection, direct-view all-glass picture tube which provides a 19-1/8 by 14-3/16-inch picture for television applications. In this tube, a magnetic focusing unit which is an integral part of the electron gun permits a sharp over-all focus adjustable through a wide range of anode voltage by a shunt sleeve around the tube neck. An external ion-trap magnet is not required and should not be used. Other features of this tube include a high-quality gray faceplate which increases picture contrast and detail under high ambient light conditions, a reflective aluminized screen to increase light output, and a space-saving rectangular face shape. An external conductive coating serves as a filter capacitor when grounded.

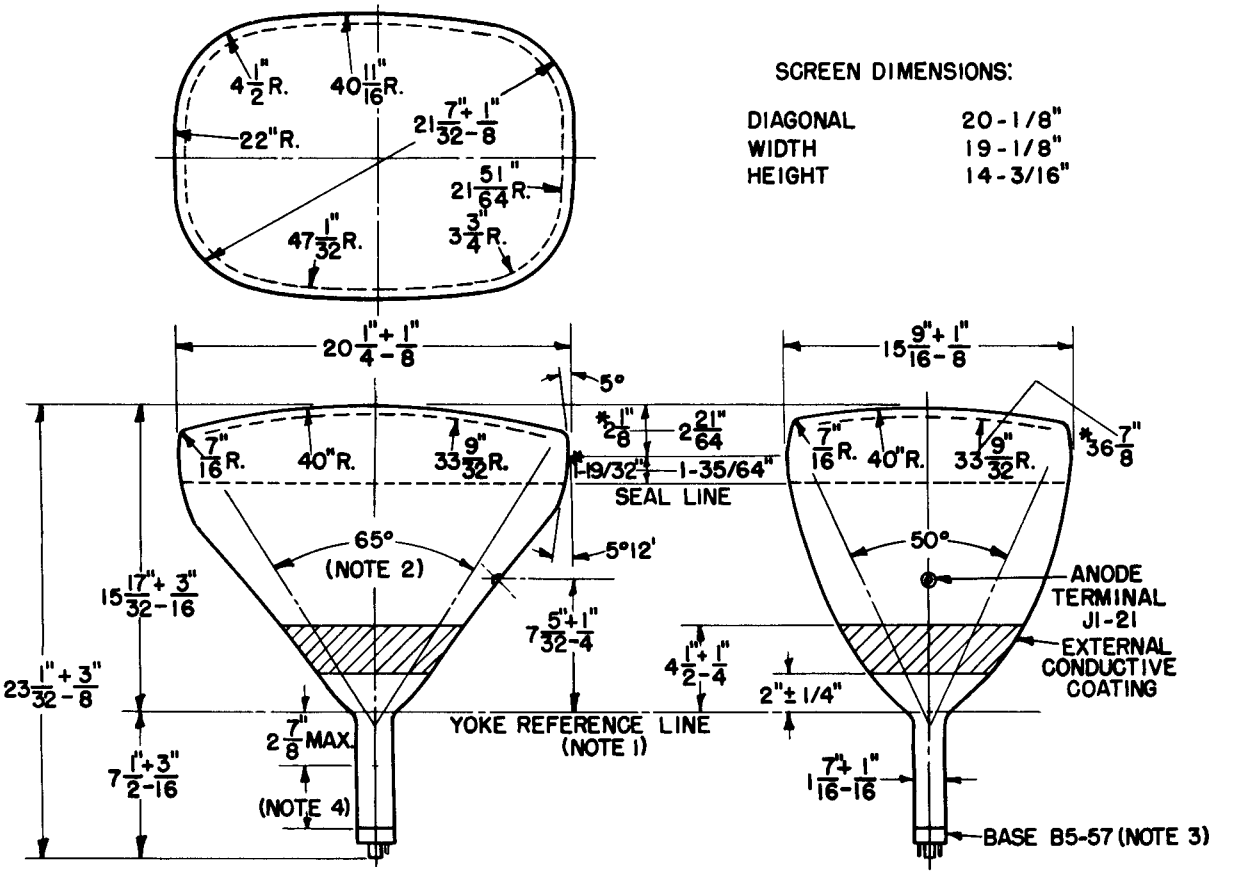
◊ The maximum ratings provide a ten-percent safety factor in accordance with the standard design-center system of rating cathode-ray tubes. The tube will withstand the combined effects of variations in line voltages and components provided the maximum design-center values are not exceeded by more than ten percent.

† Anode and grid-No. 3 which are connected together within the tube are referred to herein as anode.



If this tube is operated at voltages in excess of 16,000 volts, x-ray radiation shielding may be necessary to avert possible danger of personal injury from prolonged exposure at close range. The protective face-viewing window of apparatus using tubes of this type may provide such a safeguard. If the radiation measured in contact with this window does not exceed 6.25 milliroentgens per hour, the window will normally provide adequate protection.

‡ Anode input equals the product of anode voltage and anode current, the latter being measured at the anode contact with a direct-current ammeter.

§ Cathode should be returned to one side or to the midtap of the heater transformer winding.

Δ Optimum focusing conditions require that the tube be operated within the specified voltage range. The tube, however, will safely withstand the rated maximum anode voltage.

π For visual extinction of focused raster.

DESCRIPTION AND RATING

The 21ATP4 is an electrostatic-focus and magnetic-deflection, direct-view all-glass picture tube which provides a 19⅛- by 15-inch picture for television applications. The electron gun has a focusing voltage range of −0.4 to +2.2 percent of the anode voltage and is used with an external single-field ion-trap magnet. Other features of this tube include a high-quality gray faceplate which increases picture contrast and detail under high ambient light conditions, a reflective aluminized screen to increase light output, and a space-saving rectangular face shape. An external conductive coating serves as a filter capacitor when grounded. Except for the capacitance of this coating, the 21ATP4 is identical to the 21ALP4-A.

DESCRIPTION AND RATING

The 21BAP4 is a rectangular all-glass picture tube which provides a 19⅛- by 15-inch picture for direct-view television reception. It employs electrostatic focusing and magnetic deflection. The outstanding feature of this tube is the fact that it does not require an ion-trap magnet; thus better resolution at all times is assured. Other features of the 21BAP4 include a high-quality fluorescent screen which is aluminized to increase light output, a gray faceplate which improves picture contrast, and an external conductive coating which serves as a filter capacitor when grounded.

DEFLECTION—MAGNETIC
90-DEGREE DEFLECTION ANGLE

19⅛- BY 15-INCH PICTURE SIZE
FACEPLATE—SPHERICAL, GRAY
ALUMINIZED SCREEN
EXTERNAL CONDUCTIVE COATING

DESCRIPTION AND RATING

The 21BNP4 is a 21-inch rectangular, all-glass picture tube which provides a 19⅛- by 15-inch picture for direct-view television reception. It employs electrostatic focusing and magnetic deflection with the center of the focusing range designed to fall at or near the value of B+ voltage normally encountered in television receivers. The outstanding feature of this tube is that it requires no ion-trap magnet. This not only eliminates an external component but also avoids the aberrations inherent in ion-trap guns. Better focus and resolution are thus achieved at lower cost. In addition, the possibility of ion-trap magnet misalignment, which often causes reduced tube life, has been removed. Other features of the 21BNP4 include a high-quality fluorescent screen which is aluminized to increase light output and preclude ion-spot blemish, a gray faceplate which improves picture contrast, and a high-capacitance external conductive coating which serves as a filter capacitor when grounded.

21EP4-B—ALUMINIZED SCREEN

DESCRIPTION AND RATING

The 21EP4-A is a magnetic-focus and deflection, direct-view all-glass picture tube which provides a 19⅛- by 13⅞-inch picture for television applications. The electron gun is designed for use with an external single-field ion-trap magnet. Other features of this tube include a high-quality gray faceplate which increases picture contrast and detail under high-ambient-light conditions, a space-saving rectangular face shape, and a cylindrical front surface which materially reduces the effects of specular reflection. An external conductive coating serves as a filter capacitor when grounded.

The 21EP4-B has the additional feature of a reflective aluminized screen which increases light output.

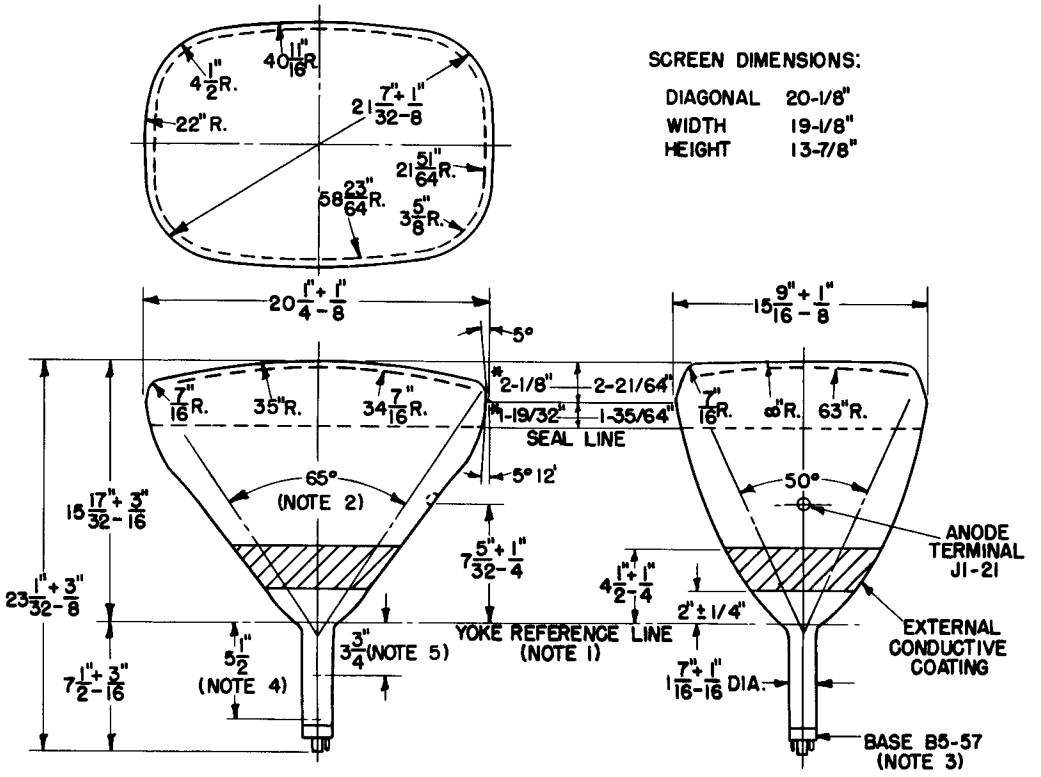
*The maximum ratings provide a ten-percent safety factor in accordance with the standard design-center system of rating cathode-ray tubes. The tube will withstand the combined effects of variations in line voltages and components provided the maximum design-center values are not exceeded by more than ten percent.

†Anode and grid-No. 3 which are connected together within the tube are referred to herein as anode.
If this tube is operated at voltages in excess of 16,000 volts, x-ray radiation shielding may be necessary to avert possible danger of personal injury from prolonged exposure at close range. The protective face-viewing window of apparatus using tubes of this type may provide such a safeguard. If the radiation measured in contact with this window does not exceed 6.25 milliroentgens per hour, the window will normally provide adequate protection.

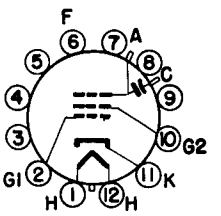


‡Cathode should be returned to one side or to the midtap of the heater transformer winding.

§Brightness and focus quality decrease with decreasing anode voltage. In general, the anode voltage should not be less than 14,000 volts.

πFor visual extinction of focused raster.

▲For JETEC focusing coil No. 109 with distance from the yoke-reference-line to center-of-air-gap equal to 3¾ inches.



♦Single-field ion-trap magnet adjusted to optimum position, equivalent to 40 milliamperes through JETEC ion-trap magnet No. 117.

NOTES:

1. REFERENCE LINE IS DETERMINED BY THE PLANE OF THE UPPER EDGE OF THE REFERENCE-LINE GAGE (RETMA NO. 110) WHEN THE GAGE IS RESTING ON THE CONE.
2. DEFLECTION ANGLE ON DIAGONAL IS 70 DEGREES.
3. ANODE TERMINAL ALIGNS WITH PIN-NO. 6 POSITION ±30 DEGREES.
4. APPROXIMATE POSITION OF ION-TRAP MAGNET.
5. RECOMMENDED POSITION FOR CENTER OF FOCUSING FIELD.

ION-TRAP GUN
EXTERNAL CONDUCTIVE COATING
21FP4-C—ALUMINIZED SCREEN

DESCRIPTION AND RATING

The 21FP4-A is an electrostatic-focus and magnetic-deflection, direct-view all-glass picture tube which provides a 19⅛- by 13⅞-inch picture for television applications. The electron gun has a focusing voltage range of −0.4 to +2.2 percent of the anode voltage and is used with an external single-field ion-trap magnet. Other features of this tube include a high-quality gray faceplate which increases picture contrast and detail under high-ambient-light conditions, a space-saving rectangular face shape, and a cylindrical front surface which materially reduces the effects of specular reflection. An external conductive coating serves as a filter capacitor when grounded.

The 21FP4-C has the additional feature of a reflective aluminized screen which increases light output.

MAXIMUM RATINGS

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Triode-Pentode

21LR8

FOR TV VERTICAL-DEFLECTION OSCILLATOR AND AMPLIFIER APPLICATIONS

The 21LR8 is a triode-pentode containing a high-mu triode and a beam pentode. The triode is designed for service as a vertical-deflection oscillator, and the pentode as a vertical-deflection amplifier in television receivers. The 21LR8 utilizes a T-12 bulb and features a 9-pin glass button base with a 0.687-inch pin circle.

Except for heater characteristics, the 21LR8 is identical to the 6LR8.

DESCRIPTION AND RATING

The 21MP4 is an electrostatic-focus, magnetic-deflection, direct-view picture tube which provides an 18⅛ by 13$\frac{11}{16}$-inch picture for television applications. The electron gun has a focusing-voltage range of −0.4 to +2.2 percent of the anode voltage and is designed for use with an external single-field ion-trap magnet. Other features of the 21MP4 include a lightweight metal-cone envelope, a high-quality frosted gray faceplate to prevent specular reflection and increase picture contrast, and a space-saving rectangular face shape.

19⅛- BY 14$\frac{3}{16}$-INCH PICTURE SIZE
FACEPLATE—SPHERICAL, GRAY
ION-TRAP GUN
EXTERNAL CONDUCTIVE COATING
21ZP4-B—ALUMINIZED SCREEN

DESCRIPTION AND RATING

The 21ZP4-A is a magnetic-focus and deflection, direct-view all-glass picture tube which provides a 19⅛- by 14$\frac{3}{16}$-inch picture for television applications. The electron gun is designed for use with an external single-field ion-trap magnet. Other features of this tube include a high-quality gray faceplate which increases picture contrast and detail under high-ambient-light conditions, and a space-saving rectangular face shape. An external conductive coating serves as a filter capacitor when grounded.

The 21ZP4-B has the additional feature of a reflective aluminized screen which increases light output.

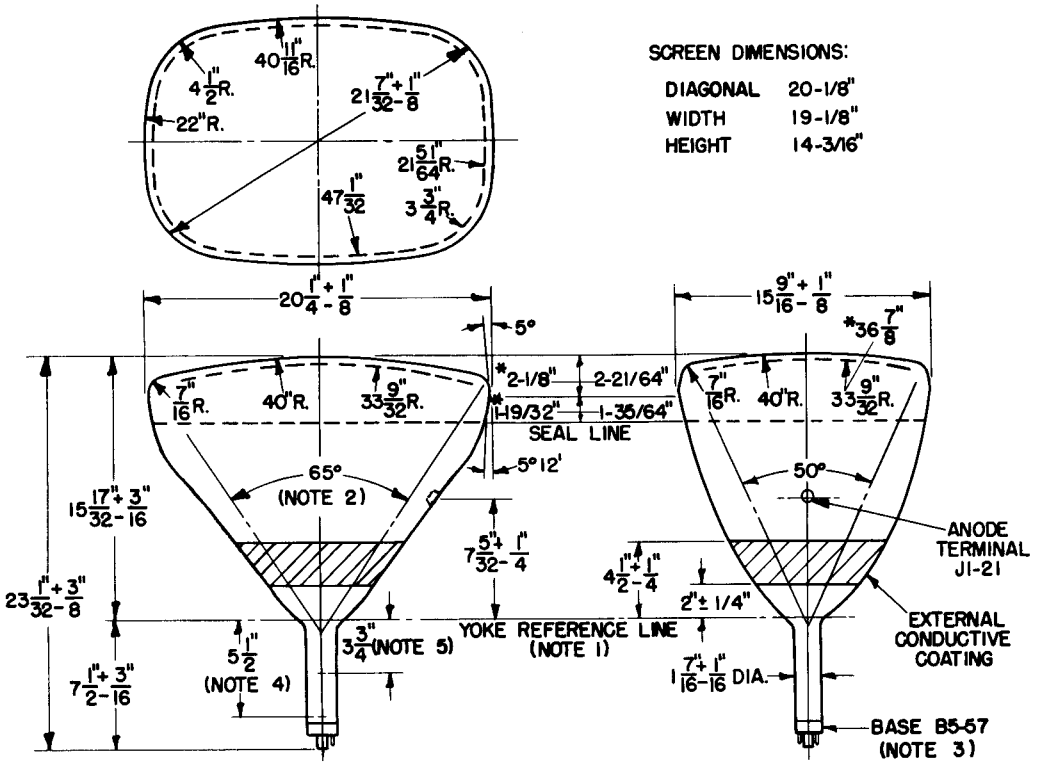
MAXIMUM CIRCUIT VALUES

Grid-No. 1 Circuit Resistance	1.5 Max	Megohms

*The maximum ratings provide a ten-percent safety factor in accordance with the standard design-center system of rating cathode-ray tubes. The tube will withstand the combined effects of variations in line voltages and components provided the maximum design-center values are not exceeded by more than ten percent.

†Anode and grid-No. 3 which are connected together within the tube are referred to herein as anode.

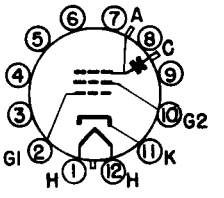
If this tube is operated at voltages in excess of 16,000 volts, x-ray radiation shielding may be necessary to avert possible danger of personal injury from prolonged exposure at close range. The protective face-viewing window of apparatus using tubes of this type may provide such a safeguard. If the radiation measured in contact with this window does not exceed 6.25 milliroentgens per hour, the window will normally provide adequate protection.



‡Cathode should be returned to one side or to the midtap of the heater transformer winding.

§Brightness and focus quality decrease with decreasing anode voltage. In general, the anode voltage should not be less than 14,000 volts.

πFor visual extinction of focused raster.



▲For JETEC focusing coil No. 109 with distance from the yoke-reference-line to center-of-air-gap equal to 3¾ inches.

♦Single-field ion-trap magnet adjusted to optimum position, equivalent to 40 milliamperes through JETEC ion-trap magnet No. 117.

NOTES:

1. REFERENCE LINE IS DETERMINED BY THE PLANE OF THE UPPER EDGE OF THE REFERENCE-LINE GAGE (RETMA NO. 110) WHEN THE GAGE IS RESTING ON THE CONE.
2. DEFLECTION ANGLE ON DIAGONAL IS 70 DEGREES.
3. ANODE TERMINAL ALIGNS WITH PIN-NO. 6 POSITION ±30 DEGREES.
4. APPROXIMATE POSITION OF ION-TRAP MAGNET.
5. RECOMMENDED POSITION FOR CENTER OF FOCUSING FIELD.

Compactron Diode

22BW3

FOR TV DAMPING DIODE APPLICATIONS

- DIFFUSION BONDED CATHODE
- 5000 VOLTS DC
- 175 MILLIAMPERES DC

The 22BW3 is a compactron, single heater-cathode type diode intended for service as the damping diode in the horizontal deflection circuit of television receivers.

The diffusion bonded cathode practically eliminates one of the major failure mechanisms in damping diodes, which is plate-to-cathode arcing caused by emissive particles being pulled from the cathode by the high electrostatic field.

MAXIMUM RATINGS

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

CATHODE RAY TUBE

23 INCH, RECTANGULAR, GLASS	FACE PLATE -- SPHERICAL GRAY
FOCUS -- ELECTROSTATIC	NON ION TRAP GUN
92 DEGREE MAGNETIC DEFLECTION	ALUMINIZED SCREEN
INTEGRAL IMPLOSION PROTECTION	EXTERNAL CONDUCTIVE COATING

LOW GRID NO. 2 VOLTAGE TYPE
FOR CATHODE-DRIVE OPERATION

DESCRIPTION AND RATING

The 23DLP4 is a 23 inch rectangular glass picture tube employing integral implosion protection consisting of a face rim band, tension strap and bulb funnel coating. An outstanding feature is a non-ion trap gun designed for operation at a low Grid #2 voltage for use in cathode-drive circuits. The fluorescent screen is aluminized to increase light output and reduce undesirable screen charging. An external conductive coating serves as a filter capacitor when grounded and contributes to the reduction of sweep induced radiation. Overall length is 18±3/8 inches and screen area is 282 square inches.

The 23DLP4 is equivalent to the 23AWP4 electrically and mechanically except for the addition of integral implosion protection hardware and reduced transmission of the face glass to provide equivalent transmission of conventional face glass plus separate protective shield.

Compactron Dissimilar-Double-Triode Pentode

23Z9

- VERTICAL OUTPUT PENTODE
- 140 VOLTS B+
- VERTICAL OSCILLATOR
- SYNC CLIPPER

The 23Z9 is a compactron containing a medium-mu triode, a high-mu triode, and a high-perveance beam pentode. The pentode is intended for vertical output service in monochrome television receivers operating from 140 volts B+. The two triodes are intended for vertical oscillator and sync clipper functions.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

DESCRIPTION AND RATING

The 24ALP4 is a 24-inch electrostatic-focus and magnetic-deflection glass picture tube. Outstanding features include a short over-all length, a small neck diameter and a non-ion-trap gun. The fluorescent screen is aluminized to increase light output and reduce undesirable screen charging. An external conductive coating is provided to serve as a filter capacitor, when grounded.

Grid-No. 2 Circuit Resistance	0.1 Min	Megohms
Focusing-Electrode Circuit Resistance	0.1 Min	Megohms

Protective resistance in the grid-No. 2 and focusing-electrode circuits is advisable to prevent damage to the tube. If applicable, one resistor common to both circuits may be used.

* Heater warm-up time required for the voltage across the heater terminals to increase to 5.0-volts in the JETEC test circuit, with E = 25-volts and R = 31.5-ohms.

† The maximum ratings provide a ten-percent safety factor in accordance with the standard design-center system of rating cathode-ray tubes. The tube will withstand the combined effects of variations in line voltage and components provided the design-center values are not exceeded by more than ten percent.

‡ Anode, grid-No. 3, and grid-No. 5, which are connected together within the tube, are referred to herein as anode.

If this tube is operated at voltage in excess of 16,000 volts, x-ray radiation shielding may be necessary to avert possible danger of personal injury from prolonged exposure at close range. The protective face-viewing window of apparatus using tubes of this type may provide such a safeguard. If the radiation measured in contact with this window does not exceed 6.25 milliroentgens per hour, the window will normally provide adequate protection.

§ Brightness and focus quality decrease with decreasing anode voltage. In general, the anode voltage should not be less than 15,000 volts.

△ For visual extinction of focused raster.

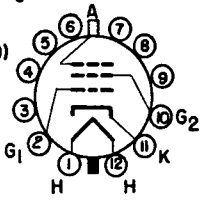
MAXIMUM CIRCUIT VALUES



Grid-No. 1 Circuit Resistance	1.5 Max	Megohms

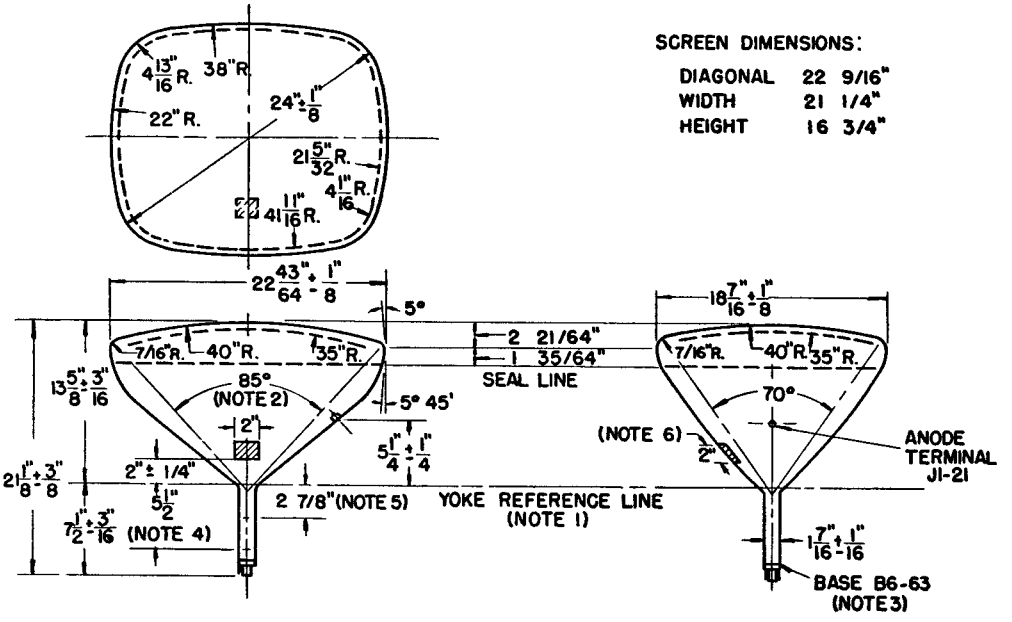
*The maximum ratings provide a ten-percent safety factor in accordance with the standard design-center system of rating cathode-ray tubes. The tube will withstand the combined effects of variations in line voltage and components provided the maximum design-center values are not exceeded by more than ten percent.

†Anode, grid-No. 3, and grid-No. 5 which are connected together within the tube are referred to herein as anode.

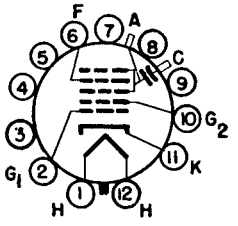
If this tube is operated at voltages in excess of 16,000 volts, x-ray radiation shielding may be necessary to avert possible danger of personal injury from prolonged exposure at close range. The protective face-viewing window of apparatus using tubes of this type may provide such a safeguard. If the radiation measured in contact with this window does not exceed 6.25 milliroentgens per hour, the window will normally provide adequate protection.



‡Cathode should be returned to one side or to the midtap of the heater transformer winding.

§Brightness and focus quality decrease with decreasing anode voltage. In general, the anode voltage should not be less than 14,000 volts.

πThe focusing electrode may be modulated within the stipulated maximum range without damage to the tube.



△For visual extinction of focused raster.

♦Single-field ion-trap magnet adjusted to optimum position, equivalent to 40 milliamperes through RETMA ion-trap magnet No. 117.

NOTES:

1. REFERENCE LINE IS DETERMINED BY THE PLANE OF THE UPPER EDGE OF THE SHOULDER OF THE REFERENCE-LINE GAGE (RETMA NO. 116) WHEN THE GAGE IS RESTING ON THE CONE.
2. DEFLECTION ANGLE ON DIAGONAL IS 90 DEGREES.
3. ANODE TERMINAL ALIGNS WITH PIN-NO. 6 ± 30 DEGREES.
4. APPROXIMATE POSITION OF ION-TRAP MAGNET.
5. APPROXIMATE POSITION OF CENTERING MAGNET, IF USED.
6. EXTERNAL CONDUCTIVE COATING CONTACT AREA.

Beam Pentode

FOR TV HORIZONTAL-DEFLECTION AMPLIFIER APPLICATIONS

24LQ6

DARK HEATER | PLATE CURRENT 30 WATTS | NOVAR TYPE | OVERLOAD Pb 200 WATTS

The 24LQ6 is a beam–power pentode primarily designed for use as the horizontal–deflection amplifier in color television receivers. Control testing gives the assurance the 24LQ6 is capable of withstanding a 200 watt plate dissipation for 40 seconds, sufficient time to permit conventional receiver protective devices to function.

The 24LQ6 has a maximum plate dissipation rating of 30 watts, a maximum grid–No. 2 input rating of 5 watts and a 0.600 ampere/24.0 volt heater having a controlled 11 second warm–up time for use in series heater–string arrangement .

NOTES

• Measured without external shield in accordance with the current issue of EIA Standard RS–191.

* With grid No. 3 and grid No. 2 connected, respectively to cathode and plate at socket.

⊕ Conditions: $E_b = E_{c2} = 145$ V, $E_{c1} = -35$ V.

• Conditions: $E_b = E_{c2} = 125$ V, $E_{c1} = -25$ V.

♦ This value can be measured by a method involving a recurrent waveform such that the Maximum Ratings of the tube will not be exceeded.

‡ Total continuous or accumulated time not to exceed 40 seconds.

† This rating is applicable when the duratoin of the vol–tage pulse does not exceed 15% of one horizontal scann –ing cycle. In a 525–line, 30–frame system, 15% of one scanning cycle is 10 μ s.

In horizontal–delecftion–amplifier service, a positive voltage should be applied to grid No. 3 to reduce in–terference from "snivets", which may occur in both vhf and uhf television receivers, and to increase power putput. A typical value is 30 V.

▲ An adequate bias resistor or other means is required to protect the tube in the absence of excitation.

§ Under pulse–duration condition specified in Footnote †.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

DESCRIPTION AND RATING

The 24YP4 is an electrostatic-focus and magnetic-deflection, direct-view all-glass picture tube which provides a 21¼ by 16¾-inch picture for television applications. The electron gun has a focusing-voltage range of −0.4 to +2.2 percent of the anode voltage and was designed for use with an external single-field ion-trap magnet. Other features of the 24YP4 include a high-quality gray faceplate to increase picture contrast and detail under high ambient light conditions, a space-saving rectangular face shape, and a fluorescent screen which is aluminized to increase light output. A high-capacitance external conductive coating serves as a filter capacitor when grounded.

BEAM PENTODE

FOR TV HORIZONTAL-DEFLECTION AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 25DN6 is a beam-power pentode designed primarily for use as the horizontal-deflection amplifier in television receivers which incorporate large-deflection-angle picture tubes. Features of the tube include high perveance, high plate current at low plate and screen voltages, and a high ratio of plate to screen current. As a result of its controlled heater warm-up characteristic, the 25DN6 is especially suited for use in television receivers that employ 600-milliampere, series-connected heaters.

Electronic TUBES

25EC6

BEAM PENTODE

DESCRIPTION AND RATING

The 25EC6 is a beam-power pentode designed for use as the horizontal-deflection amplifier in television receivers that employ 110-degree-deflection picture tubes. Designed especially for use in receivers that operate from off-the-line rectifiers, the tube features high performance capabilities at relatively low supply voltages. It has electrical characteristics similar to those of the 25CD6-GB. In addition, the 25EC6 features a controlled heater warm-up characteristic to make it especially suited for use in television receivers that employ 600-milliampere series-connected heaters.

Design-Maximum Ratings are the limiting values expressed with respect to bogie tubes at which satisfactory tube life can be expected to occur for the types of service for which the tube is rated. Therefore, the equipment designer must establish the circuit design so that initially and throughout equipment life no design-maximum value is exceeded with a bogie tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, and environmental conditions.

25L6-GT—12L6-GT—50L6-GT

BEAM PENTODE

For AF Power Amplifier Applications

DESCRIPTION AND RATING

The 25L6-GT is a beam pentode designed for use in the audio-frequency power output stage of radio and television receivers. Features include high power sensitivity and high efficiency at relatively low plate and screen voltages.

The 12L6-GT, 25L6-GT, and 50L6-GT are alike except for heater ratings and heater-cathode voltage ratings. The 50L6-GT is particularly suited for use in a-c/d-c receivers; while the 12L6-GT, as a result of its controlled heater warm-up characteristic, is especially suited for use in television receivers which employ series-connected heaters. When the 12L6-GT is used in conjunction with other 600-milliampere types which exhibit essentially the same heater warm-up characteristic, heater voltage surges across the individual tubes are minimized during the warm-up period.

ELECTRONIC INNOVATIONS IN ACTION

TUBES

Compactron Beam Pentode

26LX6

FOR TV HORIZONTAL-DEFLECTION AMPLIFIER APPLICATIONS

- COLOR TV TYPE
- 33 WATTS PLATE DISSIPATION
- 280 VOLTS B+
- 400 MILLIAMPERES DC CATHODE CURRENT
- OVER 1 AMPERE PEAK CURRENT

The 26LX6 is a compactron beam-power pentode primarily designed for use as the horizontal-deflection amplifier in color television receivers. It is characterized by having a very low knee with a very high peak current of over an ampere. This results in a basic capability to scan 90-degree large screen color picture tubes at 25 KV from 280-volt power supplies. Its low knee minimizes "snivets" without the necessity of supplying special voltages to the beam plates.

MAXIMUM RATINGS

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

NOTES

* Heater voltage for a bogey tube at If = 0.6 amperes.

‡ The equipment designer should design the equipment so that heater current is centered at the specified bogey value, with heater supply variations restricted to maintain heater current within the specified tolerance.

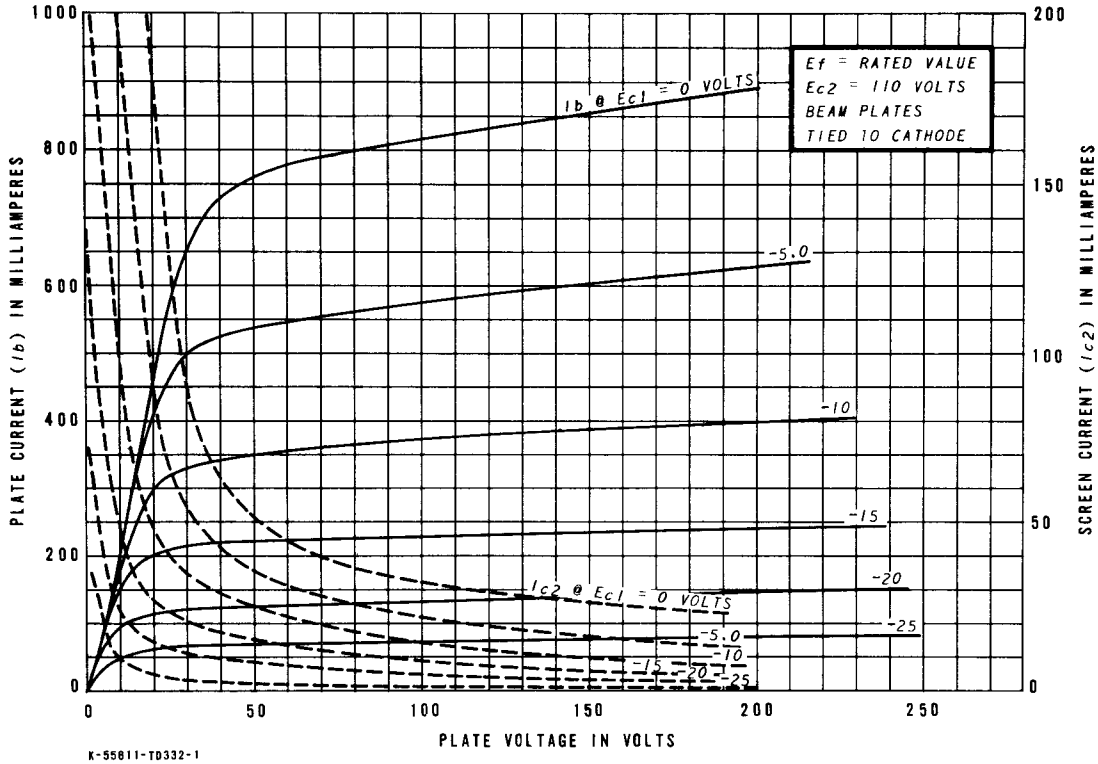
§ The time required for the voltage across the heater to reach 80 percent of the bogey value after applying 4 times the bogey heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the bogey heater voltage divided by the bogey heater current.

¶ Without external shield.

\# For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

Δ In stages operating with grid-leak bias, an adequate cathode-bias resistor or other suitable means is required to protect the tube in the absence of excitation.

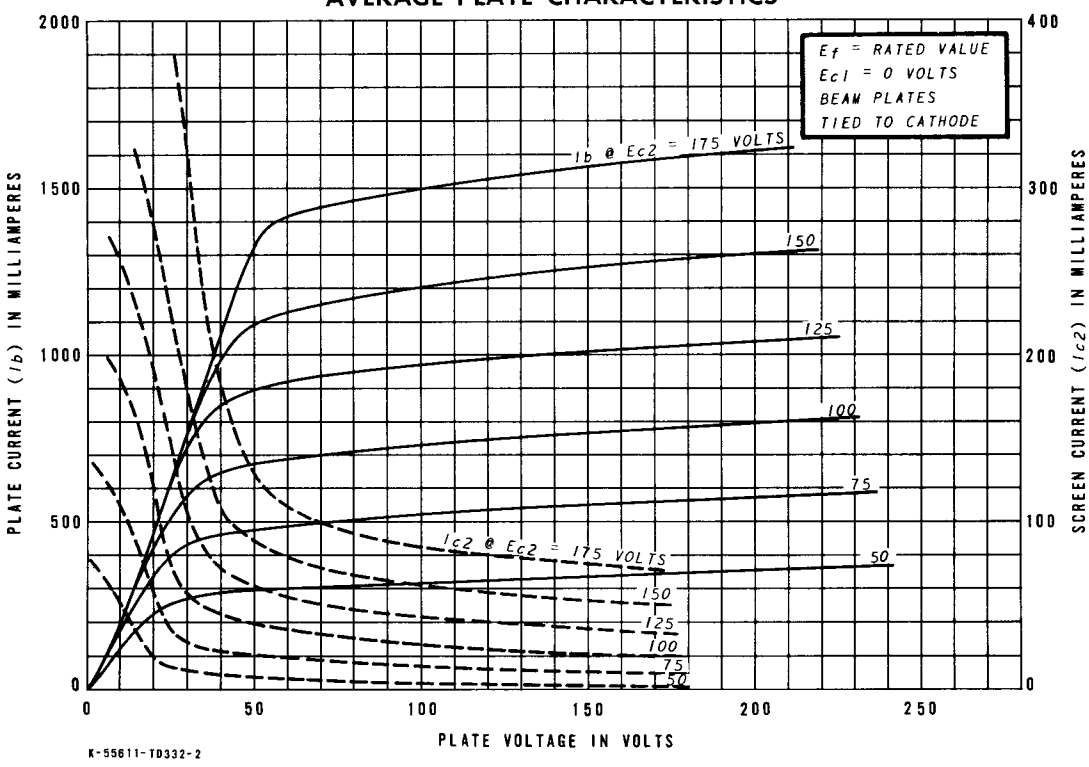
¢ The circuit design has to be such that negative control grid currents up to 5 microamperes do not have any detrimental effect upon tube adjustment or circuit performance. Care should be taken so that the limiting values for plate dissipation, screen dissipation and cathode current are not exceeded with 5 microamperes grid current.



** Measured with an infrared thermometer, Ircon Model 700 BC or equivalent, at an ambient temperature of 40° C.

‡‡ Values measured by a method involving a recurrent waveform such that the plate and screen dissipations will be kept within ratings in order to prevent damage to the tube.

§§ Triode connection (screen tied to plate) with Eb = Ec2 = 175 volts, and Ec1 = -21 volts.



The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

DESCRIPTION AND RATING

The 27EP4 is a magnetic-focus and deflection, direct-view all-glass picture tube which provides a 24- by 18½-inch picture for television applications. The electron gun is designed for use with an external single-field ion-trap magnet. Other features of this tube include a high-quality gray faceplate which increases picture contrast and detail under high-ambient-light conditions, a reflective aluminized screen to increase light output, and a space-saving rectangular face shape.

*The maximum ratings provide a ten-percent safety factor in accordance with the standard design-center system of rating cathode-ray tubes. The tube will withstand the combined effects of variations in line voltages and components provided the maximum design-center values are not exceeded by more than ten percent.

†Anode and grid-No. 3 which are connected together within the tube are referred to herein as anode.
If this tube is operated at voltages in excess of 16,000 volts, x-ray radiation shielding may be necessary to avert possible danger of personal injury from prolonged exposure at close range. The protective face-viewing window of apparatus using tubes of this type may provide such a safeguard. If the radiation measured in contact with this window does not exceed 6.25 milliroentgens per hour, the window will normally provide adequate protection.
‡Cathode should be returned to one side or to the midtap of the heater transformer winding.
§Brightness and focus quality decrease with decreasing anode voltage. In general, the anode voltage should not be less than 14,000 volts.
πFor visual extinction of focused raster.
▲For JETEC focusing coil No. 109 with distance from the yoke-reference-line to center-of-air-gap equal to 3¾ inches.
♦Single-field ion-trap magnet adjusted to optimum position, equivalent to 40 milliamperes through JETEC ion-trap magnet No. 117.

ION-TRAP GUN
EXTERNAL CONDUCTIVE COATING
ALUMINIZED SCREEN

DESCRIPTION AND RATING

The 27RP4 is a magnetic-focus and deflection, direct-view all-glass picture tube which provides a 24- by 18½-inch picture for television applications. The electron gun is designed for use with an external single-field ion-trap magnet. Other features of this tube include a high-quality gray faceplate which increases picture contrast and detail under high-ambient-light conditions, a reflective aluminized screen to increase light output, and a space-saving rectangular face shape. An external conductive coating serves as a filter capacitor when grounded.

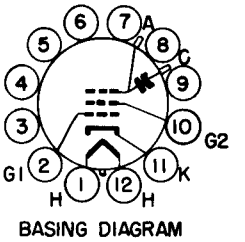
MAXIMUM CIRCUIT VALUES

Grid-No. 1 Circuit Resistance	1.5 Max	Megohms



*The maximum ratings provide a ten-percent safety factor in accordance with the standard design-center system of rating cathode-ray tubes. The tube will withstand the combined effects of variations in line voltages and components provided the maximum design-center values are not exceeded by more than ten percent.

†Anode and grid-No. 3 which are connected together within the tube are referred to herein as anode.
If this tube is operated at voltages in excess of 16,000 volts, x-ray radiation shielding may be necessary to avert possible danger of personal injury from prolonged exposure at close range. The protective face-viewing window of apparatus using tubes of this type may provide such a safeguard. If the radiation measured in contact with this window does not exceed 6.25 milliroentgens per hour, the window will normally provide adequate protection.
‡Cathode should be returned to one side or to the midtap of the heater transformer winding.
§Brightness and focus quality decrease with decreasing anode voltage. In general, the anode voltage should not be less than 14,000 volts.
πFor visual extinction of focused raster.
▲For JETEC focusing coil No. 109 with distance from the yoke-reference-line to center-of-air-gap equal to 3¾ inches.
♦Single-field ion-trap magnet adjusted to optimum position, equivalent to 40 milliamperes through JETEC ion-trap magnet No. 117.

NOTES:

1. REFERENCE LINE IS DETERMINED BY THE PLANE OF THE UPPER EDGE OF THE SHOULDER OF THE REFERENCE-LINE GAGE (RETMA NO. 116) WHEN THE GAGE IS RESTING ON THE CONE.
2. DEFLECTION ANGLE ON DIAGONAL IS 90 DEGREES.
3. ANODE TERMINAL ALIGNS WITH PIN-NO. 6 POSITION ± 30 DEGREES.
4. APPROXIMATE POSITION OF ION-TRAP MAGNET.
5. RECOMMENDED POSITION FOR CENTER OF FOCUSING FIELD.
6. EXTERNAL CONDUCTIVE COATING CONTACT AREA.

30JZ6

Compactron Beam Pentode

30JZ6 Compactron Beam Pentode. The 30JZ6 is a compactron beam power pentode designed for use as the horizontal-deflection amplifier in television receivers. A separate connection is provided for the beam plates to minimize "snivets".

Except for heater characteristics, the 30JZ6 is identical to the 6JZ6.

MAXIMUM RATINGS

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

32HQ7

Compactron Diode-Pentode

■ MULTIFUNCTION ■ LOW HEATER POWER ■ DIFFUSION BONDED DIODE CATHODE

The 32HQ7 is a multifunction compactron containing a high-perveance diode and a beam power pentode. The diode is intended for service as the damping diode and the pentode as the horizontal-deflection amplifier in television receivers.

The diode of the 32HQ7 features a diffusion bonded cathode coating. This coating practically eliminates one of the failure mechanisms in damper diodes, which is back-emission from the anode due to emissive particles being pulled from the cathode by the high electrostatic field.

FOOTNOTES

* Heater voltage for a bogey tube at If = 0.45 amperes.

† The equipment designer should design the equipment so that heater current is centered at the specified bogey value, with heater supply variations restricted to maintain heater current within the specified tolerance.

‡ The time required for the voltage across the heater to reach 80 percent of the bogey value after applying 4 times the bogey heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the bogey heater voltage divided by the bogey heater current.

§ Without external shield.

¶ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cyle of the voltage pulse must not exceed 15 percent of one scanning cycle.

\# In stages operating with grid-leak bias, an adequate cathode-bias resistor or other suitable means is required to protect the tube in the absence of excitation.

Δ Applied for short interval (two seconds maximum) so as not to damage tube.

** Triode connection (screen tied to plate) with Eb = Ec2 = 130 volts and Ec1 = -22.5 volts.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

—PRODUCT INFORMATION—

Compactron Diode-Pentode

33GY7-A

The 33GY7-A is a compactron containing a high-perveance diode and a beam-power pentode. The diode is intended for service as the damping diode and the pentode as the horizontal-deflection amplifier in television receivers.

The 33GY7-A is unilaterally interchangeable with the 33GY7 and differs only in utilizing a dimple anode construction to minimize snivets.

MAXIMUM RATINGS

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Compactron Diode

34CE3

FOR TV DAMPING DIODE APPLICATIONS

- COLOR TV TYPE
- LOW TUBE DROP
- DIFFUSION BONDED CATHODE
- 5000 VOLTS DC
- 350 MILLIAMPERES DC

The 34CE3 is a compactron containing a single heater-cathode type diode. It is intended for service as the damping diode in the horizontal deflection circuit of color television receivers.

The diffusion bonded cathode practically eliminates one of the major failure mechanisms in damping diodes, which is plate-to-cathode arcing caused by emissive particles being pulled from the cathode by the high electrostatic field.

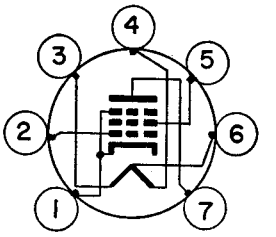
Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey tube of a specified type as defined by its published data, and should not be exceeded under the worst probable conditions.



These values are chosen by the tube manufacturer to provide acceptable serviceability of the tube, taking responsibility for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, variation in characteristics of all other tubes in the equipment, equipment control adjustment, load variation, signal variation, and environmental conditions.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

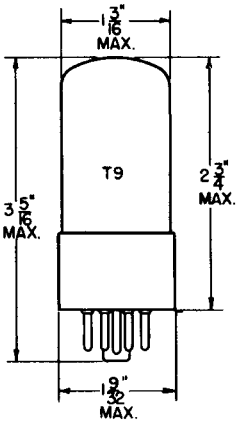
Description and Rating

HALF-WAVE HIGH-VACUUM RECTIFIER



GENERAL DESCRIPTION

Principal Application: The 35Z5-GT is a half-wave high-vacuum rectifier designed for use in a-c/d-c receivers. The heater is tapped to permit operation of a panel lamp. It is recommended that the plate be connected to the heater tap so that the plate current will pass through the panel lamp and the tapped section of the heater.

—PRODUCT INFORMATION—

Compactron Beam Pentode

36KD6

FOR TV HORIZONTAL-DEFLECTION AMPLIFIER APPLICATIONS

The 36KD6 is a compactron beam-power pentode primarily designed for use as the horizontal-deflection amplifier in color television receivers. It is characterized by having a very low knee with a very high peak current of over an ampere. This results in a basic capability to scan 90-degree large screen color picture tubes at 25 KV from 280-volt power supplies. Its low knee minimizes "snivets" without the necessity of supplying special voltages to the beam plates.

Except for heater characteristics and ratings, the 36KD6 is identical to the 6KD6.

ELECTRONIC INNOVATIONS IN ACTION

TUBES

Beam Pentode

36LW6

FOR TV HORIZONTAL-DEFLECTION AMPLIFIER APPLICATIONS

The 36LW6 beam power pentode is designed for horizontal–deflection of 90° and 110° color picture tubes from power supplies of 280 to over 400 volts. It is particularly well suited for feedback scan regulation systems since it provides high peak plate current with high screen voltage and relatively high negative end–of–scan grid drive voltage for great control latitude. The great power handling capability of the 36LW6 results from a new integral fin and radiator anode design that achieves very uniform heat distribution over the entire surface of its larger T–14 bulb. In addition, its low knee voltage minimizes snivets without the necessity of supplying special voltages to the beam plates.

Except for heater characteristics and ratings, the 36LW6 is identical to the 6LW6.

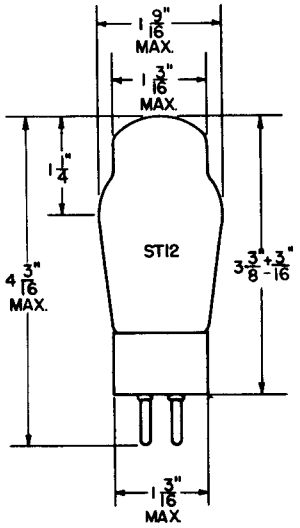
Description and Rating



POWER-AMPLIFIER PENTODE

GENERAL DESCRIPTION

Principal Application: The 41 is a heater-cathode type power-amplifier pentode tube designed for service in the output stage of a-c or battery-operated receivers. More than one audio stage preceding the 41 is not recommended because of the possibility of microphonic disturbances resulting from the high level of amplification. Electrically the 41 and 6K6-GT are identical.

Cathode	Coated Unipotential
Heater Voltage (A-C or D-C)	6.3 Volts

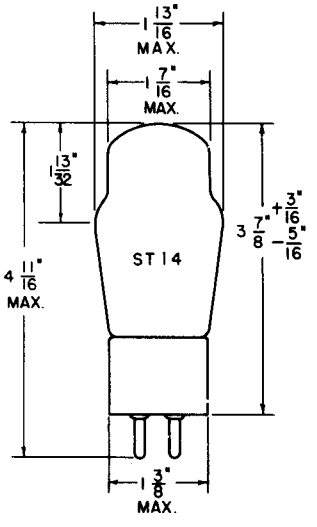
Description and Rating



POWER-AMPLIFIER PENTODE

GENERAL DESCRIPTION

Principal Application: The 42 is a heater-cathode type pentode amplifier tube designed for use as a power-amplifier in the audio-output stage of a-c or battery-operated equipment. Electrically the 42, 6F6 and 6F6-GT are identical and the 42 and 2A5 are the same except for heater rating.

50C5—12C5
17C5—25C5
BEAM PENTODE
FOR AF POWER AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 50C5 is a miniature beam pentode primarily designed for use in the audio-frequency power-output stage of radio receivers. The tube features high power sensitivity and high efficiency at relatively low plate and screen voltages normally available in this application.

The 25C5 differs from the 50C5 in heater ratings; the 12C5 and 17C5 differ from the 50C5 in heater and heater-cathode voltage ratings; in all other characteristics the four types are identical.

The controlled heater warm-up characteristic incorporated in the 12C5 and 17C5 make them especially suited for television receivers that employ series-connected heaters.

Design-Maximum Ratings are limiting values of operating and environmental conditions applicable to a bogey tube of a specified type as defined by its published data, and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, taking responsibility for the effects of changes in operating conditions due to variations in tube characteristics.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, and environmental conditions.

Design-Center ratings are limiting values of operating and environmental conditions applicable to a bogey tube of a specified type as defined by its published data, and should not be exceeded under normal conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube in average applications, taking responsibility for normal changes in operating conditions due to rated supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in tube characteristics.

The equipment manufacturer should design so that initially no design-center value for the intended service is exceeded with a bogey tube in equipment operating at the stated normal supply-voltage.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

56R9

COMPACTRON TRIODE - PENTODE

The 56R9 is a compactron containing a high-mu triode and a beam-power pentode. The triode is intended for audio-frequency voltage-amplifier service and the pentode for power-amplifier service.

A feature of the 56R9 is the incorporation of separate heaters for the two sections.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Maximum D-c Plate Voltage	450	volts
Maximum D-c Plate Current	90	milliamperes
Maximum D-c Plate Input	36	watts
Maximum D-c Grid Current	15	milliamperes
Maximum Plate Dissipation	30	watts

OSCILLATOR & RADIO-FREQUENCY POWER AMPLIFIER
Intermittent or keyed operation only.
Duration of operating period 0.1 second maximum.

Maximum D-c Plate Voltage	1100	volts
Maximum Peak D-c Plate Current	250	milliamperes
Maximum Average D-c Plate Current	25	milliamperes

OPERATING PRECAUTIONS

The VT-191 tube must not be subjected to appreciable mechanical shock or vibration. The thoriated tungsten filament of this tube is somewhat more fragile than the thoriated tungsten filaments of other transmitting tubes. These tubes should therefore be handled with more care to prevent filament breakage. In connecting to the terminals of the tube, care must be taken not to strain the glass. The tube may be supported from the terminals providing flexibility is maintained.

700E

GEC

INSTRUMENT CATHODE RAY TUBE

BRIEF DATA

The 700E has a 2 in. x 1 in. rectangular face and incorporates electrostatic focus and deflection. Low current flow to both x and y deflector plates enables numbers of tubes to be operated from common time base supplies. This together with the small dimensions of the tube and its high brightness makes the 700E particularly useful when the tube is to be used in banks for the display of digital information.

HEATER

CAPACITANCES

Cathode to all	4	pF
Grid to all	7	pF
Deflector plates x1 to x2	2	pF
Deflector plates y1 to y2	3	pF
Deflector plates x1 to all electrodes except x2	5	pF
Deflector plates y1 to all electrodes except y2	6	pF
Deflector plates x2 to all electrodes except x1	5	pF
Deflector plates y2 to all electrodes except y1	6	pF

TYPICAL OPERATION (for character generation)

First & third anode voltage	$V_{a1,3}$	2.0	kV
Second anode voltage	V_{a2}	60	V
Control grid voltage for spot cut-off	$-V_g$	60 – 100	V
Maximum x deflection factor	D_x	46.0	V/cm
Maximum y deflection factor	D_y	107.2	V/cm
Line width (typical) at I_k = 500 μA		1.5	mm

CHARACTERISTICS

		Min	Max	
Focus voltage	V_{a2}	10	45	$V/kV_{a1,3}$
Control grid voltage for spot cut-off	$-V_g$	30	50	$V/kV_{a1,3}$
X deflection factor	D_x	20.4	23.0	$V/cm/kV_{a1,3}$
Y deflection factor	D_y	44.5	53.6	$V/cm/kV_{a1,3}$
*Heater-cathode resistance	r_{h-k}	1.5		MΩ
Grid-cathode resistance	r_{g-k}	10		MΩ

*With heater ±125V to cathode.

Pattern Distortion

The edges of a test raster will lie between two concentric rectangles of 46.5 mm x 20.75 mm and 43.5 mm x 19.25 mm.

Deflection Linearity

The deflection factor for a deflection of less than 75% of the useful scan will not differ from that for a deflection of 25% by more than 2%.

Orientation

Looking at the screen with the base spigot to the left, a positive potential applied to x1 will deflect the spot to the left and a positive potential applied to y1 will deflect the spot downwards.

Focus Current

The maximum focus electrode (a2) current will be 20 μA with the tube blacked out and V_{a2} = 60 V.

Deflector Plate Current

The maximum deflector plate current will be 7 μA with a 4.5 x 2.0 cm raster and I_k = 500 μA.

Minimum Scanned Area

X axis	4.5	cm
Y axis	2.4	cm

Angle between deflection axes: 90° ± 1°.

Spot Position

The undeflected spot will lie within a circle of 3.0 mm radius centred on the tube face.

MOUNTING

The tube should not be supported by the base alone, but should preferably be held in a suitable rubber mask at the screen and by a clamp round the magnetic shield near the base.

WEIGHT

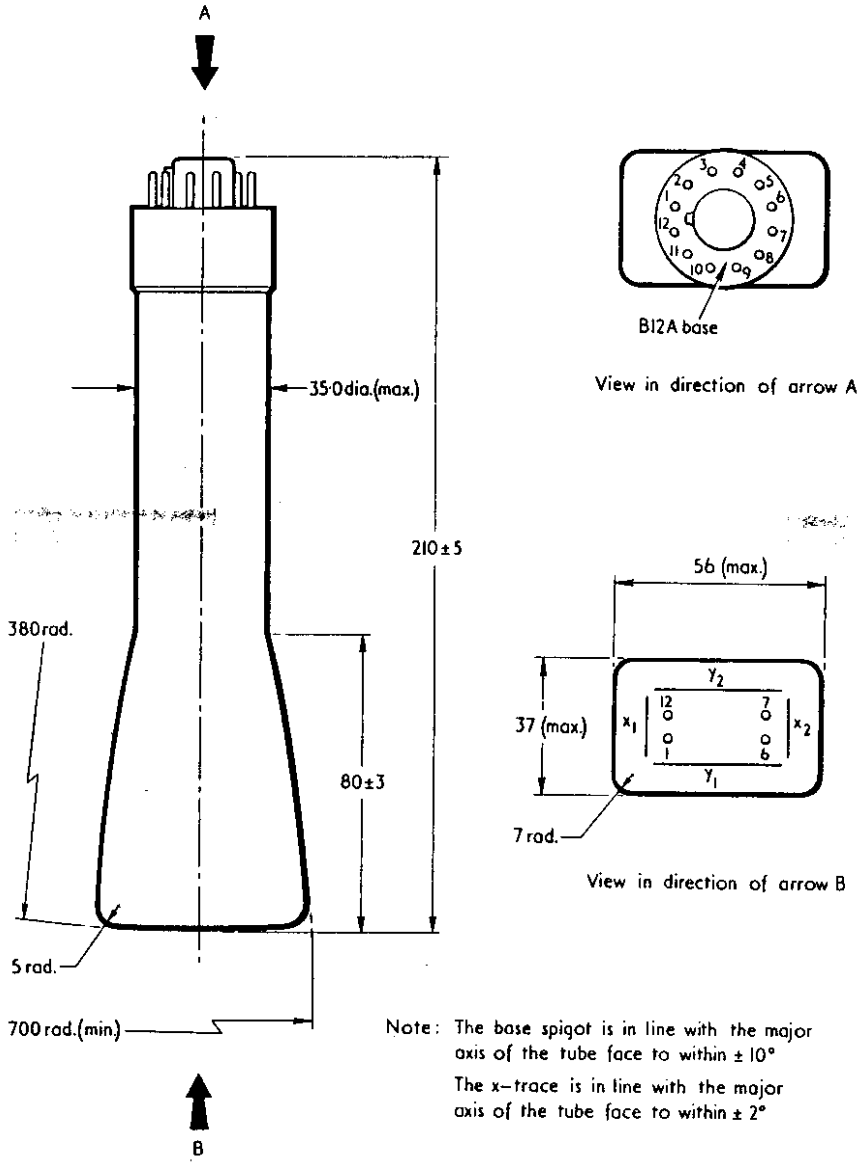
The weight of the tube is 170 g (6 oz).

BASE CONNECTIONS

Base: B12A

Pin 1:	h	Pin 7:	y_2
2:	g	8:	$a_{1,3}$
3:	k	9:	x_2
4:	a_2	10:	x_1
5:	NC	11:	NC
6:	y_1	12:	h

SOCKET



The socket should have sufficient freedom of movement to accommodate the tube overall length and base orientation tolerances.

MAGNETIC SHIELDING

The shield should be of high permeability material, of a thickness determined by the magnetic field at the tube position. The shield should be earthed. A suitable shield is available from Magnetic Shields Ltd., Headcorn Road, Staplehurst, Tonbridge, Kent.

‡ Modulation, essentially negative, may be used if the positive peak of the audio-frequency envelope does not exceed 115 per cent of the carrier conditions

The tube should be mounted so as to operate in an upright position with the filament end down.

The normal value of grid leak, when the tube is used as an oscillator or r-f power amplifier (Class C), is in the neighborhood of 5000 ohms, although this may be replaced by a suitable fixed bias. If self bias is used the cathode resistor should be approximately 500 ohms.

The maximum ratings apply only at frequencies below 6 megacycles. For operation at higher frequencies adequate ventilation and normal ambient temperatures must be maintained, and the plate voltage must be reduced as indicated.

Frequency, Megacycles	6	45	170
Percentage of Maximum Rated Plate Voltage and Plate Input	100	75	50

The resonant frequency of the grid-plate circuit is approximately 170 megacycles.

Transmitting Tube GL-862 - - Description and Rating

TECHNICAL INFORMATION

The GL-862 is a three-electrode power tube designed for use as a radio-frequency amplifier, oscillator, or Class B modulator. The plate is water-cooled and is capable of dissipating 50 to 100 kw, depending upon the class of service in which the tube is operated.

CHARACTERISTICS AND RATINGS

Filament Voltage	33	Volts
Filament Current	207	Amperes
Amplification Factor	48	
Grid-plate Transconductance, I_b = 3.0	17200	Micromhos
Direct Interelectrode Capacitances:		
Grid-plate	75	μμf
Input	52	μμf
Output	2	μμf
Frequency for Maximum Ratings	1.6	Megacycle
Type of Cooling	Water	
Net Weight (approx)	30	Pounds

MAXIMUM RATINGS AND TYPICAL OPERATING CONDITIONS

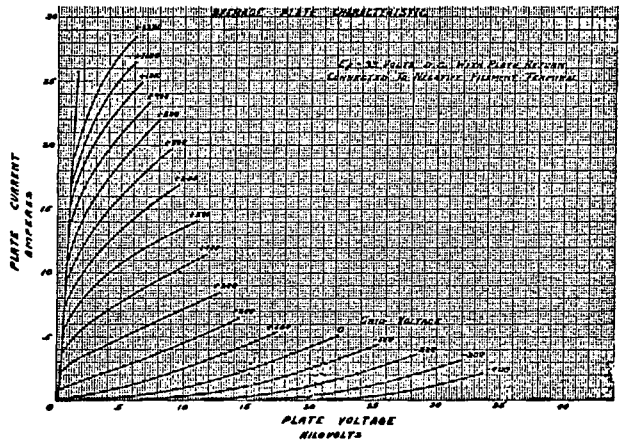
CLASS B A-F POWER AMPLIFIER (TWO TUBES):

D-c Plate Voltage	12000	15000 max	Volts
Maximum Signal Plate Current (per tube)*		7.5 max	Amperes
D-c Maximum Signal Plate Input (per tube)*		100 max	Kilowatts
Plate Dissipation (per tube)*		50 max	Kilowatts
D-c Grid Voltage	0		Volts
Peak A-f Grid Input Voltage	2000		Volts
Zero Signal Plate Current	3		Amperes
Maximum Signal Plate Current	13		Amperes
Maximum Signal Plate Input*	156		Watts
Maximum Signal Driving Power (approx)	450		Watts
Effective Load Resistance (plate-to-plate)	1800		Ohms
Maximum Signal Plate Power Output	90		Kilowatts

CLASS B R-F POWER AMPLIFIER:
Carrier conditions per tube for use with a maximum modulation factor of 1.0

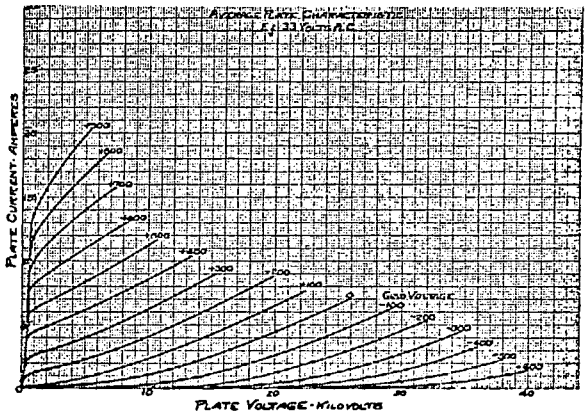
D-c Plate Voltage	12000	15000	18000	20000 max	Volts
D-c Grid Voltage	-100	-150	-200		Volts
D-c Plate Current	2.8	3.5	4.2	5.0	Amperes
Plate Input				100 max	Kilowatts
Plate Dissipation				75 max	Kilowatts
Peak R-f Grid Input Voltage	500	625	750		Volts
Driving Power (approx)**	0.5	0.75	1.1		Kilowatt
Plate Power Output	11	17.5	25		Kilowatts

CLASS C R-F POWER AMPLIFIER AND OSCILLATOR - PLATE-MODULATED:
Carrier conditions per tube for use with a maximum modulation factor of 1.0



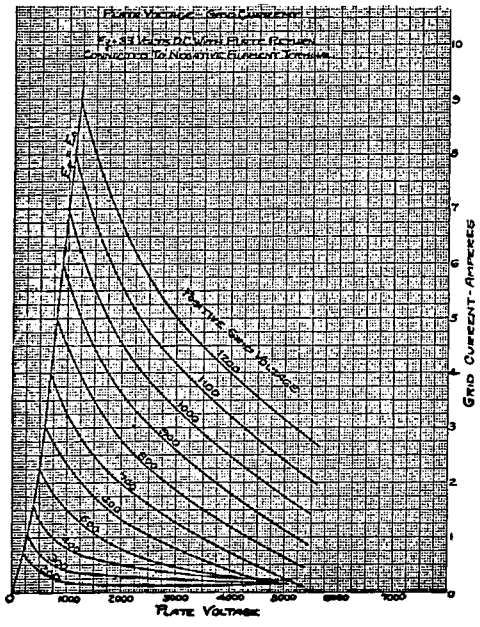
D-c Plate Voltage	8000	10000	12000	12000 max	Volts
D-c Grid Voltage	-700	-750	-800	-3000 max	Volts
D-c Plate Current	4	4.5	5	5.0 max	Amperes
D-c Grid Current (approx)	1	1	1	1.25 max	Ampere
Plate Input				60 max	Kilowatts
Plate Dissipation				50 max	Kilowatts
Peak R-f Grid Input Voltage(approx)	1700	1850	2000		Volts
Driving Power (approx)	1.7	1.85	2		Kilowatts
Plate Power Output	24	34	45		Kilowatts

from RMA release #335, April 26, 1943



CLASS C R-F POWER AMPLIFIER AND OSCILLATOR:
Key-down conditions per tube without modulation #

D-c Plate Voltage	12000	15000	18000	20000 max	Volts
D-c Grid Voltage	-800	-900	-1000	-3000 max	Volts
D-c Plate Current (approx)	6.25	7.5	8.33	10 max	Amperes
D-c Grid Current (approx)	0.8	0.85	0.9	1.0 max	Ampere
Plate Input				200 max	Kilowatts
Plate Dissipation				100	Kilowatts
Peak R-f Grid Input Voltage(approx)	2050	2300	2550		Volts
Driving Power (approx)	1.6	2	2.4		Kilowatts
Plate Power Output	50	75	100		Kilowatts



* Averaged over an audio-frequency cycle.
** At crest of audio-frequency cycle.
# Modulation, essentially negative, may be used if the positive peak of the audio-frequency envelope does not exceed 115 per cent of the carrier conditions.

Transmitting Tube GL-893 - - Description and Rating

Technical Information

The GL-893 is a three-electrode, water-cooled vacuum tube designed for use as a radio-frequency amplifier, oscillator, or Class B modulator. A particular advantage of this tube is the unique construction of the filament which permits operation from single-phase, three-phase, or six-phase alternating current, or from direct current, for all classes of service.

CHARACTERISTICS AND RATINGS

ELECTRICAL

Filament Voltage, per strand		10	Volts
Filament Current, per terminal		61	Amperes

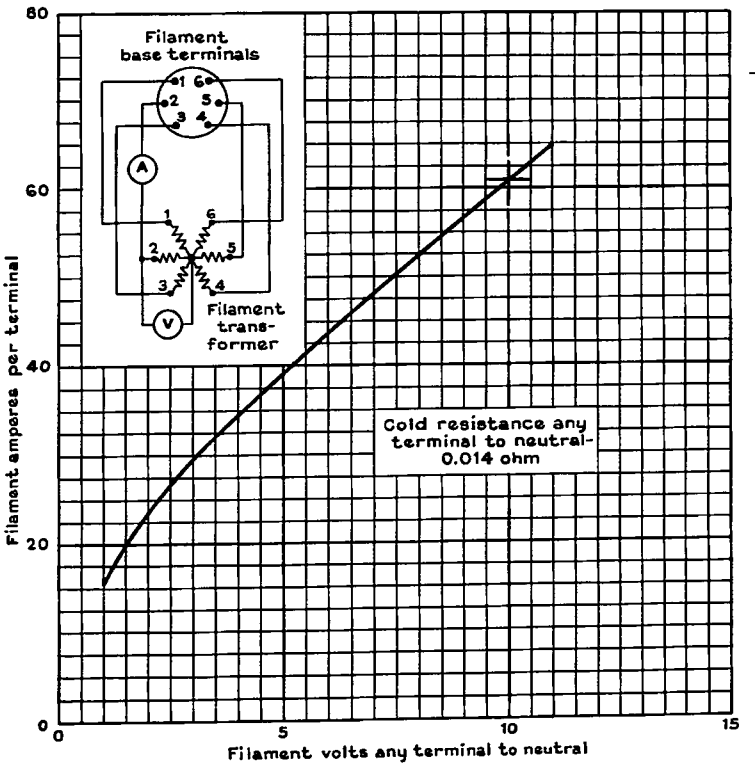
* Averaged over any audio-frequency cycle.

** At crest of audio-frequency cycle.

\# Modulation, essentially negative, may be used if the positive peak of the audio-frequency envelope does not exceed 115 per cent of the carrier conditions.



GL-893 can be operated at maximum ratings in all classes of service at frequencies as high as 5 megacycles. The tube may be operated at higher frequencies provided the maximum values of plate voltage and power input are reduced as the frequency is raised (Other maximum ratings are the same as shown under CHARACTERISTICS and RATINGS.) The tabulation below shows the highest percentage of maximum plate voltage and power input that can be used up to 40 mc for the various classes of service. Special attention should be given to adequate ventilation of the bulb at these frequencies.

FREQUENCY	5	20	40	Mc
MAXIMUM PERMISSIBLE PERCENTAGE OF MAXIMUM RATED PLATE VOLTAGE AND PLATE INPUT:

Y deflection factor	Dy	16	10.8	$V/cm/kV_{a3}$
X deflection factor	Dx	23	18.3	$V/cm/kV_{a3}$
Astigmatism correction voltage	$V_{a3\text{-}y\ mean}$	+83	−83	V/kV_{a3}
Pattern correction voltage	$V_{s\text{-}x\ mean}$	+83	−83	V/kV_{a3}

TYPICAL OPERATION (All operating potentials are with respect to cathode)

Fourth anode voltage	V_{a4}	6.0	kV
Third anode voltage	V_{a3}	600	V
Focus voltage	V_{a2}	140–240	V
First anode voltage	V_{a1}	600	V
Control grid voltage for spot cut-off.	$-V_{g1}$	65–25	V
Nominal blanking plate voltage	V_{g2}	600	V
Nominal geometry correction voltage	V_s	600	V
Maximum y deflection factor	Dy	9.6	V/cm
Maximum x deflection factor	Dx	13.8	V/cm
Line width (typical)74 screen		0.35	mm

Measured by means of a shrinking raster at $I_b = 5\mu A$

DISPLAY CHARACTERISTICS (Typical Operation)

Pattern Distortion

With pattern correction applied to s, the edges of a test raster will lie between two concentric rectangles of 70mm x 50mm and 68mm x 48mm. The angle between x and y axes will be $90^\circ \pm 1^\circ$ measured at face centre.

X Deflection Linearity
The deflection factor measured over any 10mm of deflection in the appropriate axis will not vary by more than ±3½% within the minimum scanned area.

Spot Position
The focused and undeflected spot will fall within a square 10mm x 10mm centred at the geometric centre of the faceplate.

Orientation
Looking at the screen with pins 1 and 12 uppermost, a positive voltage applied to x1 will deflect the beam to the left and a positive voltage applied to y1 will deflect the beam upwards.

Minimum Scanned Area

x major axis	7.0	cm
y minor axis	5.0	cm

This area will be centred on a point which is within 3mm of the major and minor axes of the tube face.

Axis Alignment
The electrical x axis of the tube will lie within ±5° of the major axis of the faceplate, and may be aligned with this axis by means of the field from an axial coil placed about the cone of the tube in the region shown in the outline drawing. The maximum ampere turns required for axis alignment will be given by $11\sqrt{k}V_{a4}$.

Beam Blanking (If g2 blanking not used join pins 5 & 10 externally)
Under typical operating conditions (i.e. $V_{a1} = V_{a3} = 600V$) and for a beam current (I_b) of 5μA a potential of 50V (preferably negative) with respect to a1, applied to the blanking electrode g2, will completely cut off the beam. This electrode should not be used as a brightness control.

MOUNTING

The tube may be mounted in any position but should not be supported by the base alone. It should preferably be held in a suitable rubber mask at the screen and by a clamp around the magnetic shield near the base. The socket should have sufficient freedom of movement to accommodate the maximum overall tube length and base orientation tolerances.

WEIGHT

The weight of the tube alone is 480gm (approx.).

4 in. (10cm) DOUBLE-GUN OSCILLOSCOPE TUBE (1074H)

The 1000H is a 4 in. dia. high sensitivity double gun tube with helical post deflection acceleration. It is intended for use in general purpose oscilloscopes where two independent signals are displayed on a common time base. The tube is also available with an aluminised screen giving higher trace brightness.

Mullard E10-12/E10-13C similar but not identical.

Used in Telequipment D43

Mullard
E10-12GH

CAPACITANCES

$c_{k\text{-all}}$:	5pF	$c_{x2\text{-all less x1}}$:	3.7pF	
$c_{g\text{-all}}$:	8.3pF	$c_{x1\text{-all less x2}}$:	3.7pF	4.0
$c_{x1\text{-x2}}$:	3.7pF	$c_{y1\text{-all less y2}}$:	3.3pF	
$c_{y1\text{-y2}}$:	2.0pF	$c_{y2\text{-all less y1}}$:	3.3pF	3.5
		$c_{\text{beam blanking}}$:	12.0pF	

TYPICAL OPERATION

V_{a4}	4.5	kV	3.0
*V_{a3}	1.2	kV	1.0
V_{a2} (for focus)	360	V	260
V_{a1}	1.2	kV	1.0
$-V_g$ (for cut-off)	54	V	-55
S_x	19.5	V/cm	220
S_y	7.25	V/cm	28
Line width	0.35	mm	0.5
†$V_{\text{isolation shield}}$	1.2	kV	1.0
length	386	mm	410

*It is recommended that individual adjustment of the a_3 potential be provided for astigmatism control.

†The inner end of the helix and the isolation shield are connected together inside the tube. With the correct potentials on these electrodes, barrel and pin cushion effects are minimised.

Superimposition of traces. The vertical traces may be superimposed along the vertical diameter by adjustment of the relative potentials of the trace registration electrode and a_1.

An adjustment of the position of the y traces at extreme x-deflection may be effected by adjustment of the cathode potentials. A maximum difference of $20V/kV_{a3}$ is required.

Flyback suppression (Re-trace blanking). A potential of $50V/kV_{a1}$ negative with respect to a_1 applied to the beam blanking electrode will completely cut off both beams. This electrode should not be used as a trace brightness control.

CHARACTERISTICS

V_{a2} (for focus)	200 to 400		V per $kV_{a1,3}$
$-V_g$ (for cut-off)	30 to 60		V per kV_{a1}
*S_x	15.0 to 17.5		V/cm per kV_{a3}
*S_y	5.4 to 6.67		V/cm per kV_{a3}
†$r_{h\text{-}k}$ (min)	1.5		MΩ
$r_{g\text{-}k}$ (min)	10		MΩ
Post accelerator helix resistance:	50 to 350		MΩ
$V_{\text{isolation shield}}$	967 to 1017		V per kV_{a3}

*The undeflected spots will lie within two circles of 4mm radius whose centres lie on the y axis ± 8mm from the centre of the tube face.

Minimum scan amplitude:

x:	8cm
y (each gun):	6cm
y (overlap) :	4cm

The centre of the 8cm x 4cm overlap rectangle will fall within a circle of 3mm radius from the centre of the tube face.

Minimum useful screen diameter:	9.5cm
Angle between deflection axes of each gun:	90° ± ½
Angle between deflection axes of the two guns:	x: ½° max y: ½° max

*Deflection linearity. The deflection factor for a deflection of less than 75% of the useful scan will not differ from that for a deflection of 25% by more than 2%.

*Pattern distortion. The edges of a test raster will lie between two concentric rectangles of 70mm x 40mm and 68.6mm x 39mm.

*At post accelerator ratio $V_{a4}/V_{a3} = 4$.

†With heater ±125V to cathode.

The deflector plates are designed for symmetrical operation. The y plates may intercept part of the beam and low impedance deflection should be employed.

MAGNETIC SHIELDING

The shield should be of high permeability material, of a thickness determined by the magnetic field at the tube position. The shield should be earthed. Suitable shields are available from Oliver & Randall Co. Ltd., Telcon Metals Ltd., and Magnetic & Electrical Alloys Ltd.

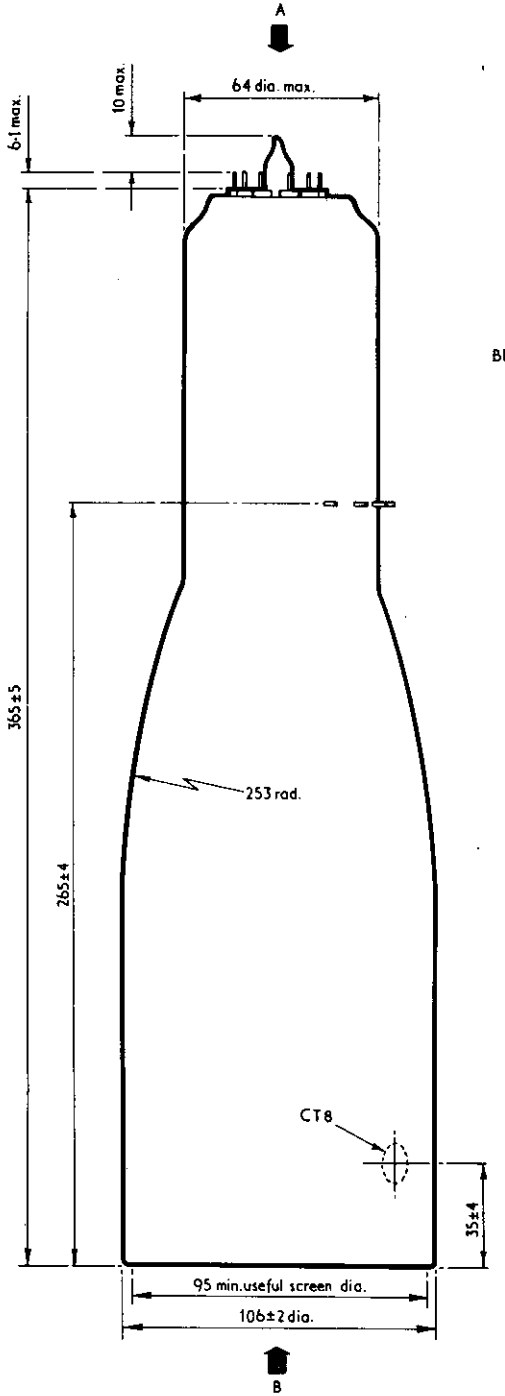
MOUNTING

The tube should not be supported by the base alone, but should preferably be held in a suitable rubber mask at the screen and by a clamp round the magnetic shield near the base. Rubber masks are available from the Standard Insulator Co. Ltd.

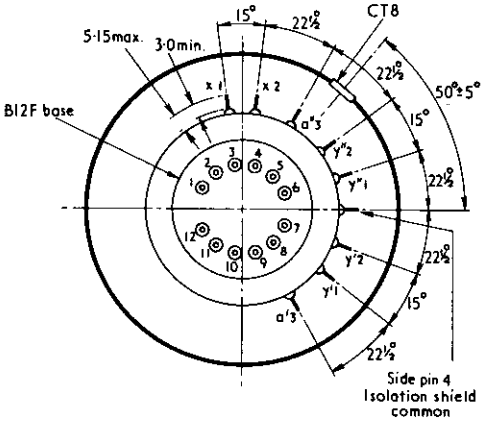
SOCKET

The socket should have sufficient freedom of movement to accommodate the tube overall length and base orientation tolerances.

Suitable sockets are available from Carr Fastener Co. Ltd. (Type 77/842).



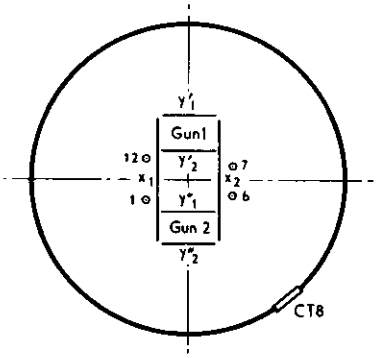
For the side contact and side pins, suitable connectors may be obtained from Carr Fastener Co. Ltd. (Type 77/699 and 75/602 respectively).



ORIENTATION

Looking at the screen with pins 9 and 10 of the base uppermost, a positive potential applied to x_1 will deflect the spot to the left and a positive potential applied to y_1 will deflect the spot upwards.

WEIGHT



2¼ lb (1 kg approx).

View in direction of arrow A

Note: each pin can vary by 2½° in any direction. The X–trace can vary by ±5° with respect to the CT8 side contact.

View in direction of arrow B

The position of the CT8 side contact relative to the contour of the bulb conforms to BS448:1953, section 6/18.

*Line width typical		0.6	mm

*Measured by means of a microscope at the centre of x and y axes for each gun, at a beam current of 1.0 μA.

†The wall coating, m, and the mean potential of the deflector plates are normally held constant at a3 potential. Adjustment of the a'3 and a''3 potentials relative to the mean potential of the deflector plates may be used as an astigmatism control.

DISPLAY CHARACTERISTICS (Typical operation)

Spot Position

The undeflected spots will lie within two 10 mm dia. circles whose centres lie on the y axis ± 12.5 mm from the geometric centre of the tube face.

Minimum Scanned Area

Minimum useful scanned area is ±57 mm along the axes intersecting at the centre of the tube face.

Deflection Linearity

The difference between the deflection sensitivity for 25 % and 75 % of the useful scanned area will not be greater than 2 % for each gun.

Pattern Distortion

The edges of a test raster 72 mm x 72 mm will lie between two concentric squares of 68 mm and 72 mm sides.
Angle between deflection axes of each gun is 90 ° ± 1 °. Angle between the x deflection axes of the two guns is not greater than 1 °.

Orientation

Looking at the screen with pin 10 uppermost, a positive potential applied to x1 will deflect the spot to the left and a positive potential applied to y1 will deflect the spot upwards.

MOUNTING

The tube may be mounted in any position but must not be supported by the base alone. It should, preferably, be held in a suitable rubber mask at the screen and by a clamp round the magnetic shield near the base. The socket should have sufficient freedom of movement to accommodate overall length and base orientation tolerances.

WEIGHT

The weight of the tube alone is approximately 1.1 kg (2½ lb).

Maximum x deflection factor	D_x	21.0	V/cm
*Typical line width (for type 24 phosphor		0.4	mm

*Measured by means of a shrinking raster at the geometric centre of the face-plate.

DISPLAY CHARACTERISTICS

Minimum Scanned Area

x axis	10	cm
y (each gun)	6	cm
y (overlap)	4	cm

The centre of the 10 x 4 cm overlap rectangle will fall within a circle of 3 mm radius centred on the geometric centre of the faceplate.

Beam Blanking

A potential of 50 V/kV_{a1} (preferably negative) with respect to a1 applied to the blanking electrode g3, will completely cut off both beams. This electrode should not be used as a brightness control.

Superimposition of Traces

The vertical traces may be superimposed along the vertical diameter by adjustment of the potential of the trace registration electrode g2, relative to a1, A range of adjustment of ± 10 V/kV_{a1} may be required. Superimposition of the vertical traces at the extremes of x deflection may then be effected by adjustment of the relative cathode potentials. Provision should be made for a potential difference of up to 40 V/kV_{a3} between the two cathodes for this purpose.

Astigmatism Correction

Adjustment of the potential on a3 relative to the y deflection plate mean potential may be used for the purpose of astigmatism correction. A range of adjustment of ± 30 V/kV_{a3} should be allowed for this purpose.

Pattern Correction

Barrel or pincushion distortion may be minimised by the application of the appropriate potential to s1 relative to the x plate mean potential. A range of adjustment from −30 to +30 V/kV_{a3} should be allowed for this purpose. Astigmatism and pattern correction potentials are quoted for the condition where the x plate mean potential is equal to the y plate mean potential. If, in any application, a difference between x and y plate mean potentials is unavoidable, it is recommended that this difference should be kept to a minimum.

Pattern Distortion

For each beam with pattern correction applied, the edges of a test raster will lie between two concentric rectangles of 102 x 51 mm and 100 x 50 mm. The angle between x and y axes (each beam) will be 90 ° ± 1 °. The angle between y axes (beams superimposed) will be 0 ° ± 1.5 °.

Deflection Linearity

The deflection factor for a deflection of less than 75 % of the useful scan will not differ from that for a deflection of 25 % by more than 2 %.

Spot Position

The focused and undeflected spots will fall within two 10 mm dia. circles whose centres lie on the geometric y – axis and ±10 mm from the geometric centre of the faceplate.

Orientation

Looking at the screen with pins 9 and 10 of the base uppermost a positive potential applied to x1 will deflect the beam to the left and a positive potential applied to y1' or y1'' will deflect the appropriate beam upwards.

MOUNTING

The tube may be mounted in any position but should not be supported by the base alone. It should preferably be held in a suitable rubber mask at the screen and by a clamp round the magnetic shield near the base. The socket should have sufficient freedom of movement to accommodate the maximum overall tube length and base orientation tolerances.

y (each beam)	6	cm
y (overlap)	6	cm

Beam Blanking

A potential of $30V/kV_{a3}$ negative with respect to a1, applied to the beam blanking electrode g3 will completely cut off both beams. This electrode should not be used as a brightness control.

Beam Equality

The brightness of the traces may be equalised at low level by the application of a suitable potential to the beam equalising electrode, g2. A range of adjustment of -16,6 to +6,6 V/kV_{a1} should be allowed for this purpose.

Astigmatism Correction

Adjustment of the potentials on s1' and s1", relative to their nominal values, may be used for the purpose of independent astigmatism correction of the two traces. A range of adjustment of $\pm 14V/kV_{a3}$ should be allowed on $V_{s1'}$ and $\pm 20V/kV_{a3}$ on $V_{s1''}$ for this purpose. In order to minimise astigmatism and errors in geometry it is recommended that differences between the mean potentials of each deflection system and also a3 should be kept to a minimum.

Pattern Correction

Barrel and pincushion effects may be minimised by applying the appropriate potential to s2. However this should be kept to a minimum.

Axis Alignment

The electrical x axis of the tube will lie within ±5° of the major axis of the faceplate, and may be aligned with this axis by means of the field from an axial coil placed about the cone in the region shown in the outline drawing. The maximum ampere turns required for axis alignment will be given by $12\sqrt{kV_{a4}}$.

Background Suppression

Background illumination of the phosphor may be reduced and contrast improved by applying -20V to s_3 with respect to s_2.

DISPLAY CHARACTERISTICS

Pattern Distortion

For both beams simultaneously with no pattern correction applied, the edges of the test rasters will lie between two concentric rectangles of 100mm × 60mm and 98mm × 58mm. The angle between x and y axes (each beam) will be 90° ± 1°. The angle between y axes (beams superimposed) will be 0° ± 1,5°.

Deflection Linearity

The deflection factor for a deflection of less than 75% of the useful scan will not differ from that for a deflection of 25% by more than 2%.

Spot Position

The focused and undeflected spots will fall within a square 2,0cm × 2,0cm centred at the geometric centre of the faceplate.

The maximum displacement between the spots in the y direction will be 10mm.

Orientation

Looking at the screen with pins 1 and 12 uppermost, a positive voltage applied to x_1 will deflect the beam to the left and a positive voltage applied to y_1' or y_1'' will deflect the appropriate beam upwards.

MOUNTING

The tube may be mounted in any position but should not be supported by the base alone. It should preferably be held in a suitable rubber mask at the screen and by a clamp around the magnetic shield near the base. The socket should have sufficient freedom of movement to accommodate the maximum overall tube length and base orientation tolerances.

Measured by means of a shrinking raster at I_b = 5μA

*1374Q/G8 is a special purpose tube operating at 7.0/0.7kV

DISPLAY CHARACTERISTICS (Typical Operation)‡

‡These characteristics apply to 1374Q/G8 when suitably scaled for 7.0/0.7kV operation.

Pattern Distortion

With pattern correction applied to s_2, the edges of a test raster will lie between two concentric rectangles of 100mm x 60mm and 98mm x 58.5mm. The angle between x and y axis will be 90° ± ¾° measured at face centre.

Deflection Linearity

The deflection factor for a deflection of less than 75% of the useful scan will not differ from that for a deflection of 25% by more than 3%.

Spot Position

The focused and undeflected spot will fall within a rectangle 8mm x 20mm centred at the geometric centre of the faceplate, the greater dimension being aligned in the x-axis.

Orientation

Looking at the screen with pins 1 and 12 uppermost a positive voltage applied to x_1 will deflect the beam to the left and a positive voltage applied to y_1 will deflect the beam upwards.

Minimum Scanned Area

x major axis	10.0	cm
y minor axis	6.0	cm

This area will be centred on a point which is within 3mm of the major and minor axis of the tube face.

ASTIGMATISM CORRECTION

Adjustment of the potential on a_3 relative to the y deflector plate mean potential may be used for astigmatism correction. A range of adjustment from +30 to $-60V/kV_{a_3}$ should be allowed.

AXIS ALIGNMENT

The electrical x axis of the tube will lie within ±5° of the major axis of the faceplate, and may be aligned with this axis by means of the field from a close fitting axial coil placed about the cone of the tube in the region shown in the outline drawing. The maximum ampere turns required for axis alignment will be given by $14\sqrt{kV_{a_4}}$.

BEAM ALIGNMENT

Because of the close spacing of the deflector plates in order to achieve sensitivity, some tubes may exhibit a tendency towards x plate cut off within the specified minimum window size. This may be corrected by centralising the undeflected beam in the x deflector plates by means of a suitable potential applied to the beam aligning electrode g_3. A range of adjustment of $\pm 50V/kV_{a_1}$ with respect to a_1 should be allowed for this purpose.

BEAM BLANKING (If g_2 blanking not used join pins 7 & 10 externally)

Under typical operating conditions (i.e. $V_{a_1} = V_{a_3} = 1.0kV$) and for a beam current (I_b) of 5μA a potential of 50V (preferably negative) with respect to a_1, applied to the blanking electrode g_2, will completely cut off the beam. This electrode should not be used as a brightness control.

BACKGROUND SUPPRESSION

Background illumination may be reduced and contrast improved by applying a potential of −25V to s_3 with respect to s_2.

MOUNTING

The tube may be mounted in any position but should not be supported by the base alone. It should preferably be held in a suitable rubber mask at the screen and by a clamp around the magnetic shield near the base. The socket should have sufficient freedom of movement to accommodate the maximum overall tube length and base orientation tolerances.

WEIGHT

The weight of the tube alone is 800 gm (approx.).

Minimum Scanned Area

x	10	cm
y	6	cm

Astigmatism Correction

Adjustment of the potential on a3 relative to the y deflection plate mean potential may be used for the purpose of astigmatism correction. A range of adjustment of $\pm$ 33V/kV$_{a3}$ should be allowed for this purpose.

Pattern Correction

Barrel or pincushion distortion may be minimised by the application of the appropriate potential to s2 relative to the x plate mean potential. A range of adjustment of $\pm$ 33V/kV$_{a3}$ should be allowed for this purpose. Astigmatism and pattern correction potentials are quoted for the condition where the x plate mean potential is equal to the y plate mean potential. If, in any application, a difference between x and y plate mean potentials is unavoidable, it is recommended that this difference should be kept to a minimum.

Background Suppression

Background illumination of the phosphor may be reduced and contrast improved by applying a potential of -25V to s3 with respect to s2.

DISPLAY CHARACTERISTICS

Pattern Distortion

With pattern correction applied, the edges of a test raster will lie between two concentric rectangles of 100 $\times$ 60 mm and 98 $\times$ 58 mm.

Spot Position

The focused and undeflected spot will fall within a rectangle 12 x 20mm centred at the geometric centre of the faceplate, the greater dimension being in the x axis.

Orientation

Looking at the screen with pins 1 and 12 of the base uppermost a positive potential applied to x1 will deflect the beam to the left and a positive potential applied to y1 will deflect the beam upwards.

MOUNTING

The tube may be mounted in any position but should not be supported by the base alone. It should preferably be held in a suitable rubber mask at the screen and by a clamp round the magnetic shield near the base. The socket should have sufficient freedom of movement to accomodate the maximum overall tube length and base orientation tolerances.

*Measured by means of microscope at the geometric centre of the faceplate, at a total beam current of 10μA.

Minimum scanned area

x	10	cm
y (each beam)	6	cm
y (overlap)	5	cm

Beam Blanking

At 10μA total beam current (i.e. 5μA each beam) a potential of $45V/kV_{a3}$, negative with respect to a1, applied to the blanking electrode g2 will completely cut off both beams. This electrode should not be used as a brightness control.

Beam Equality

The brightness of the traces may be equalised at low level by means of a suitable horizontally orientated lateral magnetic field, applied in the region between grid (g1) and first anode (a1). A suitable magnet may be obtained from Electro Acoustic Industries Ltd. under Type No. BC 13.

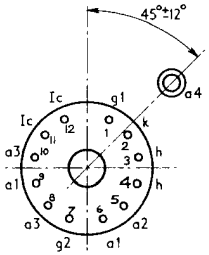
Astigmatism Correction

Adjustment of the potential on a3 relative to the y deflector plate mean potential may be used for the purpose of astigmatism correction. A range of adjustment of ±40 V/kVa3 should be allowed for this purpose.

Pattern Correction

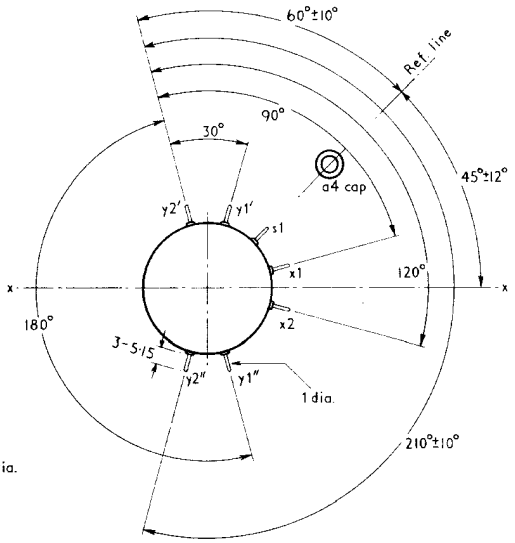
Barrel or pincushion distortion may be minimised by the application of the appropriate potential on s1 relative to the x plate mean potential. A range of adjustment of ±80 V/kVa3 should be allowed for this purpose.

DISPLAY CHARACTERISTICS



Pattern Distortion

For both beams simultaneously with no pattern correction applied, the edges of each test raster will lie between two concentric rectangles of 100mm × 60mm and 97.3mm × 58mm. The concentric rectangles are centred about the geometric vertical axis of the screen and 5mm above the geometric horizontal axis to accommodate the y' test raster and 5mm below the axis to accommodate the y" test raster. The angle between x and y axes (each beam) will be 90°± 1°, and the angle between the two y axes (beams superimposed) will be 0°±1.5°.



Deflection linearity

The deflection factor for a deflection of less than 75% of the useful scan will not differ from that for a deflection of 25% by more than 2%.

Printed in England

Spot Position

The focused and undeflected spots will fall within a rectangle 1.2cm × 2.0cm centred at the geometric centre of the faceplate, the greater dimension being aligned in the x axis. The maximum displacement between the spots in the y direction will be 5mm.

Orientation

Looking at the screen with pins 1 and 12 uppermost, a positive potential applied to x_1 will deflect the beam to the left and a positive potential applied to y_1' or y_1'' will deflect the appropriate beam upwards.

MOUNTING

The tube may be mounted in any position but should not be supported by the base alone. It should preferably be held in a suitable rubber mask at the screen and by a clamp around the magnetic shield near the base. The socket should have sufficient freedom of movement to accommodate the maximum overall tube length and base orientation tolerances.

SE CONNECTIONS

Base: B12F

GEC

INSTRUMENT CATHODE RAY TUBE

BRIEF DATA

A 13 cm flat faced, single gun, spiral p.d.a. tube for medium bandwidth applications. Features include electrostatic focus, electrostatic deflection and deflection blanking. The scan voltages required for this tube can be obtained from transistorised deflection circuits. Precision engineering renders astigmatism and geometry correction potentials unnecessary in many applications. The tube may also be used as a monoaccelerator with a larger scanned area.

	(i)	(ii)	
Final anode voltage (p.d.a.)	3	4	kV
p.d.a. ratio	3:1	4:1	
*Display area	8 x 10	8 x 10	cm
Y deflection factor (D_Y)	<8.7	<9.2	V/cm
X deflection factor (D_X)	<16.5	<18	V/cm

*Limited by a useful screen diameter of 12 cm.

HEATER

Heater voltage	6.3	V
Heater current	0.3	A

SCREEN

Y deflection factor	D_y (at $V_{a4}/V_{a3} = 4$)	9.2	7.5	$V/cm/kV_{a3}$
X deflection factor	D_x (at $V_{a4}/V_{a3} = 4$)	18	13	$V/cm/kV_{a3}$
Y deflection factor	D_y (at $V_{a4}/V_{a3} = 3$)	8.7	7.0	$V/cm/kV_{a3}$
X deflection factor	D_x (at $V_{a4}/V_{a3} = 3$)	16.5	12	$V/cm/kV_{a3}$
Astigmatism correction voltage	V_{a3}	+50	−50	V/kV_{a3}
Pattern correction voltage	V_s	+50	−50	V/kV_{a3}

TYPICAL OPERATION (All operating potentials are with respect to cathode)

		(i)	(ii)	
Fourth anode voltage	V_{a4}	3	4	kV
Third anode voltage	V_{a3}	1	1	kV
Focus voltage	V_{a2}	175–400	175–400	V
First anode voltage	V_{a1}	1	1	kV
Control grid voltage for spot cut-off	$-V_{g1}$	35–75	35–75	V
Nominal blanking plate voltage	V_{g2}	1	1	kV
Nominal geometry correction voltage	V_s	1	1	kV
Maximum y deflection factor	D_y	8.7	9.2	V/cm
Maximum x deflection factor	D_x	16.5	18.0	V/cm

DISPLAY CHARACTERISTICS (Typical Operation)

Minimum Scanned Area	(i)	(ii)	
X axis	10.5	10	cm
Y axis	8.4	8	cm

This area will be centred on a point which is within 3 mm of the centre of the tube face. The undeflected spot will lie within a 14 mm square at the centre of the tube face.

†Astigmatism Correction

Adjustment of the potential on a3 relative to the y plate mean potential may be used for the purpose of astigmatism correction. A range of adjustment of $\pm 50V/kV_{a3}$ should be allowed for this purpose.

†Pattern Correction

Barrel or pincushion distortion may be minimised by the application of the appropriate potential to s with respect to the x plate mean potential. A range of adjustment of $\pm 50V/kV_{a3}$ should be allowed for this purpose. Astigmatism and pattern correction potentials are quoted for the condition where the x plate mean potential is equal to the y plate mean potential. If in any application, a difference between x and y plate mean potentials is unavoidable it is recommended that this difference should be kept to a minimum.

†In many applications these correction potentials will be unnecessary.

Beam Blanking

At a beam current of 10 μA, a potential of +65V/kV_{a1} with respect to a1 applied to the blanking electrode g2, will completely cut off the beam. This electrode should not be used as a brightness control.

Pattern Distortion

With pattern correction applied the edges of a test raster will lie between two concentric rectangles 100 x 60 mm and 97.5 x 58.5 mm. The angle between the x and y axes will be 90° ± 1°.

Deflection Linearity

The deflection factor for a deflection of less than 75% of useful scan will not differ from that for a deflection of 25% by more than 2%.

MONOACCELERATOR OPERATION (Simple circuit)

First and third anode voltage	$V_{a1\ a3}$	2	kV
Focus voltage	V_{a2}	350–800	V
Control grid voltage for spot cut-off	$-V_{g1}$	70–150	V
Maximum y deflection factor	D_Y	13	V/cm
Maximum x deflection factor	D_X	21	V/cm
Minimum scanned area x axis		11.5	cm
y axis		10	cm

The CT8 contact and pins 5, 6, 9 and 11 must all be connected to each other when the tube is used in this way except where separate potentials are applied as previously described.

MOUNTING

The tube may be mounted in any position but should not be supported by the base alone. It should, preferably, be held in a suitable rubber mask at the screen and by a clamp round the magnetic shield near the base. The socket should have sufficient freedom of movement to accommodate overall length and base orientation tolerances.

Maximum x deflection factor	D_x	18.0	V/cm
*Line width (typical)		0.6	mm

Line width by shrinking raster 0.3

*For type 24 (P31) phosphor, measured by means of a microscope at the geometric centre of the faceplate, at a beam current of 5 μA.

DISPLAY CHARACTERISTICS

Pattern Distortion

With pattern correction applied the edges of a test raster will lie between two concentric rectangles of 100 x 80 mm and 98 x 77.5 mm.
The angle between the x and y axes will be 90° ± 1°.

Deflection Linearity

The deflection factor for a deflection of less than 75% of the useful scan will not differ from that for a deflection of 25% by more than 2%.

Spot Position

The focused and undeflected spot will fall within a rectangle 8 x 10 mm centred at the geometric centre of the faceplate, the greater dimension being parallel to the x axis.

Orientation

When looking at the screen with pins 6 and 7 of the base uppermost, a positive potential applied to x1 will deflect the beam to the left and a positive potential applied to y1 will deflect the beam upwards.

Minimum Scanned Area

x axis	10	cm
y axis	8	cm

This area will be centred on a point which is within 3 mm of the major and minor axes of the tube face.

Beam Blanking

At a cathode current of 500 μA, a potential of +60V/kV_{a1} with respect to a1 applied to the blanking electrode g2, will completely cut off the beam. This electrode should not be used as a brightness control.

Astigmatism Correction

Adjustment of the potential on a3 relative to the y plate mean potential may be used for the purpose of astigmatism correction. A range of adjustment of ±50 V/kV_{a3} should be allowed for this purpose.

Pattern Correction

Barrel or pincushion distortion may be minimised by the application of the appropriate potential to s with respect to the x plate mean potential. A range of adjustment of $\pm 50V/kV_{a3}$ should be allowed for this purpose. Astigmatism and pattern correction potentials are quoted for the condition where the x plate mean potential is equal to the y plate mean potential. If in any application, a difference between x and y plate mean potentials is unavoidable it is recommended that this difference should be kept to a minimum.

Axis Alignment

The electrical x axis of the tube will lie within $\pm 5^{\circ}$ of the major axis of the faceplate and may be aligned with this axis by means of the field from an axial coil placed about the cone of the tube in the region shown in the outline drawing. The maximum ampere turns required for axis alignment will not exceed $12\sqrt{kV_{a4}}$.

MOUNTING

The tube may be mounted in any position but should not be supported by base alone. It should, preferably, be held in a suitable rubber mask at the screen and by a clamp round the magnetic shield near the base. The socket should have sufficient freedom of movement to accommodate overall length and base orientation tolerances.

WEIGHT

The weight of the tube alone is approximately 1.0 kg.

Nominal geometry voltage	V_{s2}	1.2	kV
Nominal mesh voltage	V_{s3}	1.18	kV
Maximum y deflection factor	D_y	5.3	V/cm
Maximum x deflection factor	D_x	11.0	V/cm
‡Line width (typical) 74 screen		0.4	mm

‡Measured by means of a shrinking raster at the geometric centre of the faceplate, at a beam current of 10 μA.

DISPLAY CHARACTERISTICS (Typical operation unless stated)

Pattern Distortion
With pattern correction applied, the edges of a test raster will lie between two concentric rectangles of 100 x 80 mm and 98 x 78 mm.
The angle between x and y axes will be $90^\circ \pm 1^\circ$ measured at the face centre.

Deflection Linearity
The deflection factor, measured over any 10 mm of deflection in the appropriate axis, will not vary by more than 5% within the central 100 x 80 mm area.

Spot Position
The focused and undeflected spot will fall within a square 10 x 10 mm centred at the geometric centre of the faceplate.

Background Suppression
Background illumination may be reduced and contrast improved by applying a potential of −20 V to s3 with respect to s2.

Orientation
When looking at the screen with pins 1 and 12 of the base uppermost, a positive voltage applied to x1 will deflect the beam to the left and a positive voltage applied to y1 will deflect the beam upwards.

Minimum Scanned Area

x axis	10	cm
y axis	8	cm

Axis Alignment
The electrical x axis of the tube will lie within ± 5° of the major axis of the faceplate and may be aligned with the axis by means of the field from an axial coil placed about the cone of the tube in the region shown in the outline drawing. The maximum ampere turns required for axis alignment will not exceed $7\sqrt{kV_{a4}}$.

MOUNTING

The tube may be mounted in any position but should not be supported by the base alone. It should, preferably, be held in a suitable resilient mask at the screen and by a clamp round the magnetic shield near the base. The socket should have sufficient freedom of movement to accommodate overall length and base orientation tolerances.

BASE CONNECTIONS

Base:	B12F	Side contact (CT8):	a4
Pin 1:	g	Pin 7:	a1*
2:	k	8:	a3
3:	h	9:	s3
4:	h	10:	a1*
5:	a2	11:	s2
6:	s1	12:	IC

*Pins 7 and 10 must be connected together externally.

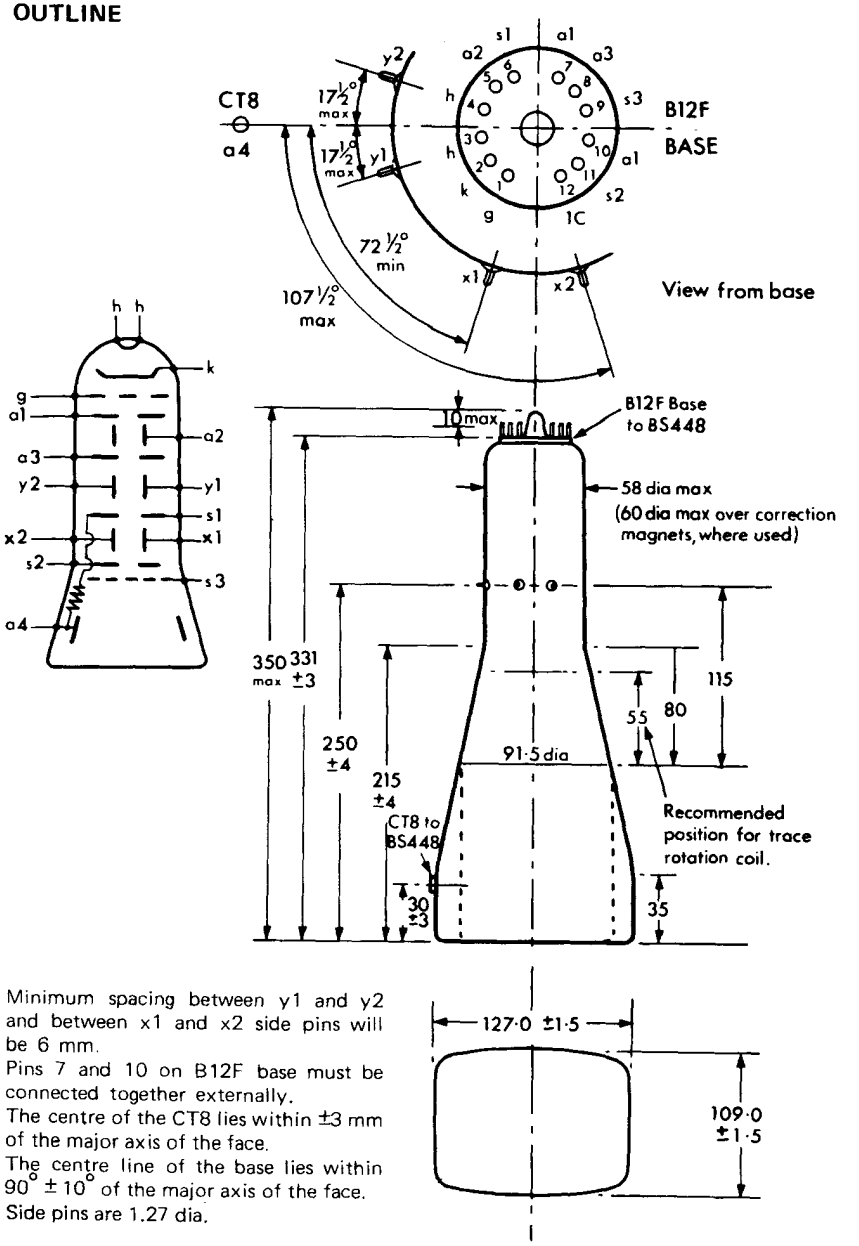
Side pin connections (use connector 50LS/156) as viewed from the base and reading clockwise from base pin 12:-

x2 x1 y1 y2

WEIGHT

The weight of the tube alone is approximately 1.15 kgm.

MAGNETIC SHIELD



A suitable magnetic shield with trace rotation coil may be obtained from Magnetic Shields Ltd., Headcorn Road, Staplehurst, Tonbridge, Kent.

WARNING

Care should be taken not to expose the tube to strong magnetic fields either in use or during storage.

Whilst M-OV has taken care to ensure the accuracy of the information contained herein it accepts no responsibility for the consequences of any use thereof and also reserves the right to change the specification of goods without notice.
M-OV accepts no liability beyond that set out in its standard conditions of sale in respect of infringement of third party patents arising from the use of tubes or other devices in accordance with information contained herein.

OUTLINE

Minimum spacing between y1 and y2 and between x1 and x2 side pins will be 6 mm.
Pins 7 and 10 on B12F base must be connected together externally.
The centre of the CT8 lies within ±3 mm of the major axis of the face.
The centre line of the base lies within $90^{\circ} \pm 10^{\circ}$ of the major axis of the face.
Side pins are 1.27 dia.

V_{a1}	1	kV
V_{g2} (nom)	1	kV
V_s (nom)	1	kV
$-V_{g1}$ (for cut-off)	35 to 65	V
D_y (max)	8·5	V/cm
D_x (max)	15·5	V/cm
*Line width (typical)	0·7	mm
" by shrinking raster	0·3 ect.	

*For type 74 (P31) phosphor, measured by means of a microscope at the geometric centre of the faceplate, at a beam current of 5μA.

Minimum Scanned Area

x	10	cm
y	8	cm

This area will be centred on a point which is within 3mm of the major and minor axes of the tube face.

Beam Blanking

At a cathode current of 500μA, a potential of $+60V/kV_{a1}$ with respect to a1, applied to the blanking electrode g2, will completely cut off the beam. This electrode should not be used as a brightness control.

Astigmatism Correction

Adjustment of the potential on a3 relative to the y plate mean potential may be used for the purpose of astigmatism correction. A range of adjustment of $\pm 50V/kV_{a3}$ should be allowed for this purpose.

Pattern Correction

Barrel or pincushion distortion may be minimised by the application of the appropriate potential to s with respect to the x plate mean potential. A range of adjustment of $\pm 50V/kV_{a3}$ should be allowed for this purpose. Astigmatism and pattern correction potentials are quoted for the condition where the x plate mean potential is equal to the y plate mean potential. If in any application, a difference between x and y plate mean potentials is unavoidable it is recommended that this difference should be kept to a minimum.

Axis Alignment

The electrical x axis of the tube will lie within $\pm 5°$ of the major axis of the faceplate and may be aligned with this axis by means of the field from an axial coil placed about the cone of the tube in the region shown in the outline drawing. The maximum ampere turns required for axis alignment will not exceed $12\sqrt{kV_{a4}}$.

DISPLAY CHARACTERISTICS

Pattern Distortion

With pattern correction applied the edges of a test raster will lie between two concentric rectangles of 100 × 80mm and 98 × 77·5mm.
The angle between the x and y axes will be 90° ±1°.

Deflection Linearity

The deflection factor for a deflection of less than 75% of the useful scan will not differ from that for a deflection of 25% by more than 2%.

Spot Position

The focused and undeflected spot will fall within a rectangle 8 × 10mm centred at the geometric centre of the faceplate, the greater dimension being parallel to the x axis.

ORIENTATION

When looking at the screen with pins 6 and 7 of the base uppermost, a positive potential applied to x1 will deflect the beam to the left and a positive potential applied to y1 will deflect the beam upwards.

MOUNTING

The tube may be mounted in any position but should not be supported by the base alone. It should, preferably, be held in a suitable rubber mask at the screen and by a clamp round the magnetic shield near the base. The socket should have sufficient freedom of movement to accommodate overall length and base orientation tolerances.

DISPLAY CHARACTERISTICS (Typical Operation)

Minimum Scanned Area	(i)	(ii)	
X axis	10	10	cm
Y axis	8	8	cm

This area will be centred on a point which is within 3 mm of the centre of the tube face.

The undeflected spot will lie within a square of side 10 mm at the centre of the tube face.

Beam Blanking

At a cathode current of 500 μA, a potential of $-65V/kV_{a1}$ with respect to a1 applied to the blanking electrode g2, will completely cut off the beam. This electrode should not be used as a brightness control.

Astigmatism Correction

Adjustment of the potential on a3 relative to the y plate mean potential may be used for the purpose of astigmatism correction. A range of adjustment of $\pm 50V/kV_{a3}$ should be allowed for this purpose.

Pattern Correction

Barrel or pincushion distortion may be minimised by the application of the appropriate potential to s with respect to the x plate mean potential. A range of adjustment of $\pm 50V/kV_{a3}$ should be allowed for this purpose. Astigmatism and pattern correction potentials are quoted for the condition where the x plate mean potential is equal to the y plate mean potential. If in any application, a difference between x and y plate mean potentials is unavoidable it is recommended that this difference should be kept to a minimum.

Axis Alignment

The electrical x axis of the tube will lie within $\pm 5^{\circ}$ of the major axis of the faceplate and may be aligned with this axis by means of the field from an axial coil placed about the cone of the tube in the region shown in the outline drawing. The maximum ampere turns required for axis alignment will not exceed $12\sqrt{kV_{a4}}$.

Pattern Distortion

With pattern correction applied, the edges of a test raster will lie between two concentric rectangles 100 x 80 mm and 97.5 x 78 mm. The angle between the x and y axes will be $90^{\circ} \pm 1^{\circ}$.

Deflection Linearity

The deflection factor for a deflection of less than 75% of useful scan will not differ from that for a deflection of 25% by more than 2%.

MOUNTING

The tube may be mounted in any position but should not be supported by the base alone. It should, preferably, be held in a suitable rubber mask at the screen and by a clamp round the magnetic shield near the base. The socket should have sufficient freedom of movement to accommodate overall length and base orientation tolerances.

OUTLINE

1056

Dimensions in mm.

IGNITRON

The GL-5553-A ignitron is a sealed, stainless-steel-jacketed, water-cooled, mercury-pool tube designed primarily for resistance-welding-control service. In this service, two tubes in the inverse-parallel connection will control 2400 kilovolt-amperes at voltages of 250 to 600 volts over the frequency range of 25 to 60 cycles. The ability of this tube to carry very high peak currents for short periods makes it especially suited to such service.

Ease of installation, economical use of space, and reliability of operation are assured by design and construction features inherent in the steel-jacketed construction.

The GL-5553-A ignitron is equivalent to a 1200-ampere magnetic contactor.

DESCRIPTION AND RATING

The 5636 is a subminiature dual-control pentode in which both grid-number 1 and grid-number 3 can be used as independent control electrodes. It is suitable for service as a gated or gain-controlled amplifier, or as a mixer at frequencies up to approximately 400 megacycles.

Intended for use in critical industrial and military applications in which operational dependability is of primary importance, the 5636 exhibits a high degree of mechanical strength and incorporates a heater-cathode construction capable of withstanding many-thousand cycles of intermittent operation. When used in on-off control applications, the tube will maintain its emission capabilities after long periods of operation under cutoff conditions.

† Design-Maximum Ratings are the limiting values expressed with respect to bogie tubes at which satisfactory tube life can be expected to occur. To obtain satisfactory circuit performance, therefore, the equipment designer must establish the circuit design so that no design-maximum value is exceeded with a bogie tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, and environmental conditions.

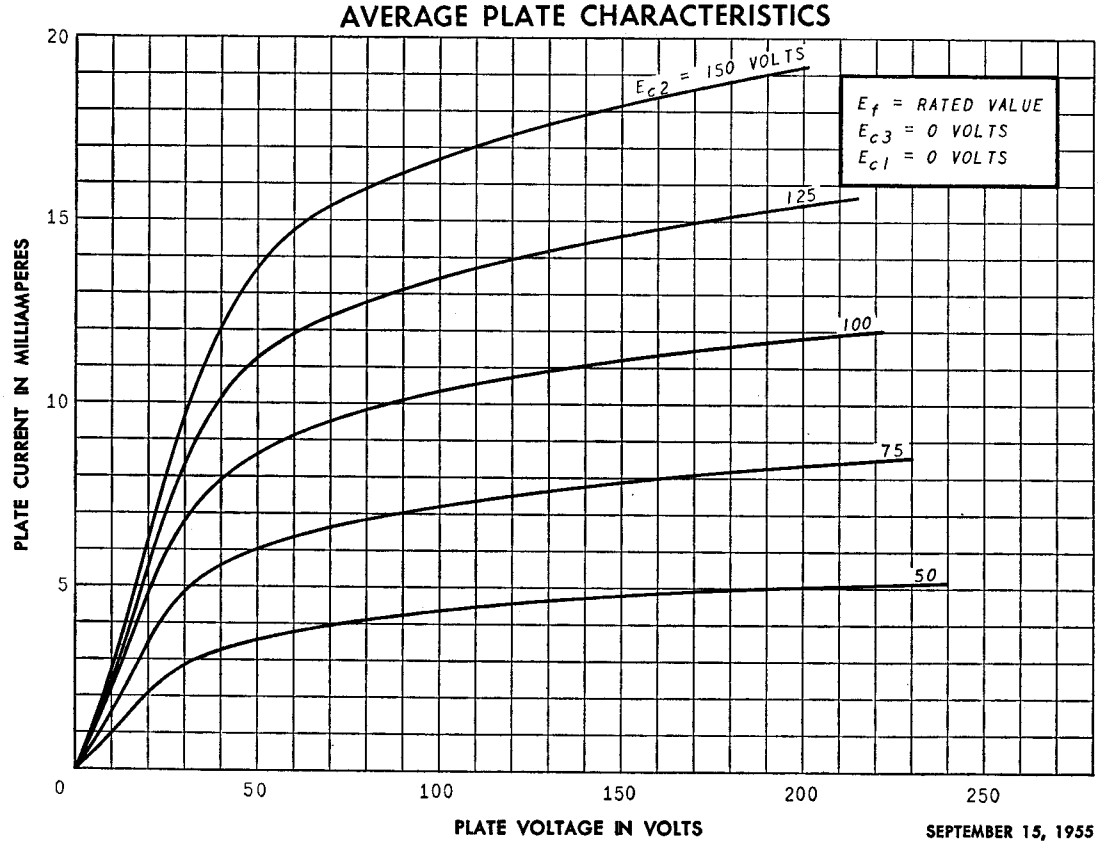
The indicated 500-hour values are life-test end points for the following conditions of operation: Ef = 6.3 volts, Eb = 100 volts, Ec2 = 100 volts, Rk = 150 ohms, Rg1 = 1.0 meg, g3 tied to k, Ehk = 200 volts with heater positive with respect to cathode, and bulb temperature = 220 C minimum.

SPECIAL TESTS AND RATINGS

Stability Life Test
Statistical sample operated for one hour to evaluate and control initial variations in transconductance.

Survival Rate Life Test
Statistical sample operated for one hundred hours to evaluate and control early-life electrical and mechanical inoperatives.

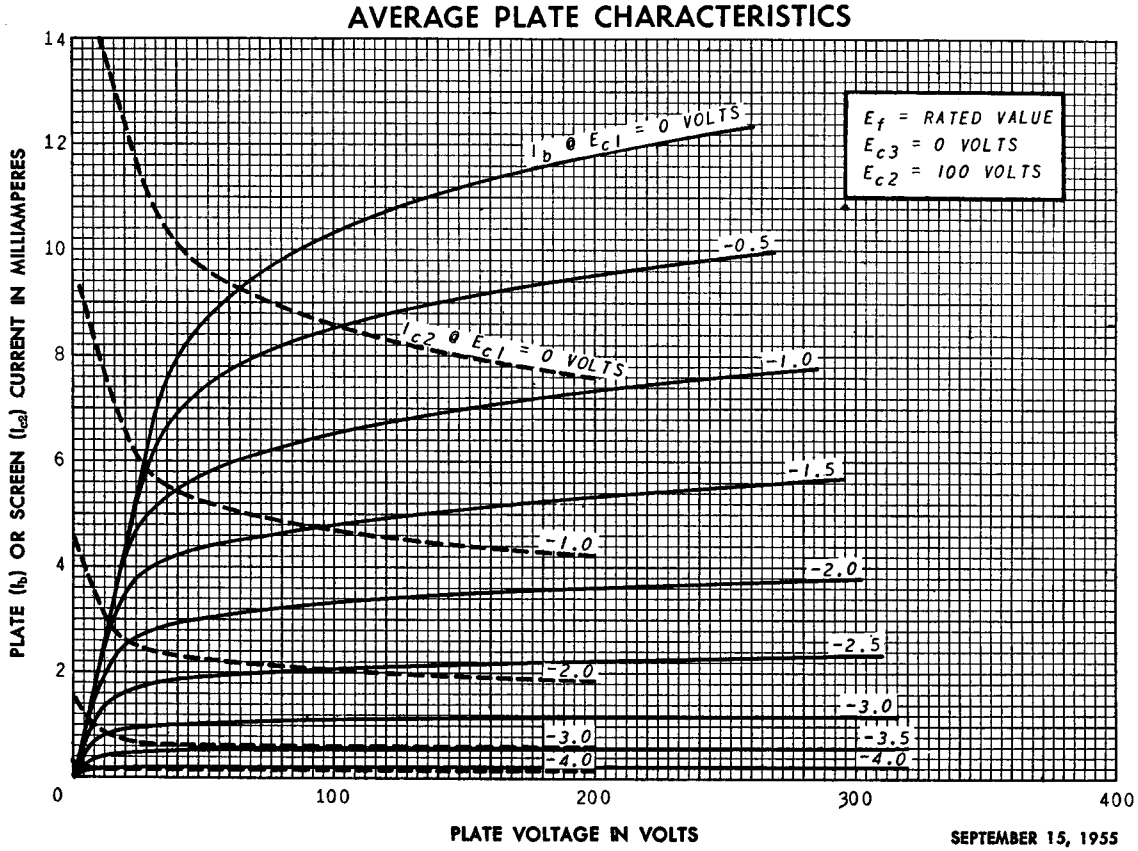
Heater-Cycling Life Test
Statistical sample operated for 2000 cycles to evaluate and control heater-cathode defects. Conditions of test include Ef = 7.0 volts cycled for one minute on and four minutes off, Eb = Ec3 = Ec2 = Ec1 = 0 volts, and Ehk = 140 volts RMS.



Shock Rating—450 G
Statistical sample subjected to five impact accelerations of 450 G in each of four different positions. The accelerating forces are applied by the Navy-type, High Impact (flyweight) Shock Machine for Electronic Devices or its equivalent.

Fatigue Rating—2.5 G
Statistical sample subjected to vibrational acceleration of 2.5 G for 32 hours minimum in each of three different positions. The sinusoidal vibration is applied at a fixed frequency between 25 and 60 cycles per second.

Altitude Rating—60,000 Feet
Statistical sample subjected to pressure of 55 millimeters of mercury to evaluate and control arcing and corona.



Note: The conditions for some of the indicated tests have deliberately been selected to aggravate tube failures for test and evaluation purposes. In no sense should these conditions be interpreted as suitable circuit operating conditions.
In the design of military equipment employing this tube, reference should be made to the appropriate MIL-E-1B specification.

HEATER-CYCLING RATING
HIGH TRANSCONDUCTANCE

DESCRIPTION AND RATING

The 5654 is a miniature sharp-cutoff pentode for use as a wide-band, high-frequency amplifier. It is also useful in video and audio amplifiers, oscillators, mixers, frequency multipliers, and cathode followers.

The 5654 is a special-quality tube intended for use in critical industrial and military applications in which operational dependability is of primary importance. Features of the tube include a high degree of mechanical strength and a heater-cathode construction capable of withstanding many-thousand cycles of intermittent operation. When used in on-off control applications, the tube will maintain its emission capabilities after long periods of operation under cutoff conditions.

Analysis of the electrical characteristics of this tube with those of the 6AK5 will indicate that the 5654 is essentially similar.

DESCRIPTION AND RATING

The 5670 is a miniature medium-mu twin triode each section of which has a separate cathode connection. The tube is suited for use in a wide-variety of general-purpose amplifier and mixer circuits as well as numerous multivibrator and oscillator applications. The useful operating range extends from low frequencies through the VHF region.

The 5670 is a special-quality tube intended for use in critical industrial and military applications in which operational dependability is of primary importance. Features of the tube include a high degree of mechanical strength and a heater-cathode construction capable of withstanding many-thousand cycles of intermittent operation. When used in on-off control applications, the tube will maintain its emission capabilities after long periods of operation under cutoff conditions.

Analysis of the electrical characteristics of this tube with those of the 2C51 will indicate that the 5670 is essentially similar.

CHARACTERISTICS LIMITS CONTINUED ON PAGE 4

CHARACTERISTICS LIMITS (Cont'd)

		Minimum	Maximum	
Vibrational Noise Output Voltage, RMS Ef = 6.3 volts, Ebb = 150 volts, Ec = −3.0 volts, R_L = 2000 ohms, vibrational acceleration = 2.5 G at 25 cps. Sections in parallel	Initial	....	100	Millivolts
Grid Emission Current, Each Section Ef = 7.5 volts, Eb = 150 volts, Ecc = −10 volts, Rg = 0.5 meg	Initial	0	0.5	Microamperes

The indicated 500-hour and 1000-hour values are life-test end points for the following conditions of operation for each section: Ef = 6.3 volts, Eb = 150 volts, Rk = 240 ohms, Rg = 0.5 meg, Ehk = 135 volts with heater positive with respect to cathode, and bulb temperature = 165 C minimum.

SPECIAL TESTS AND RATINGS

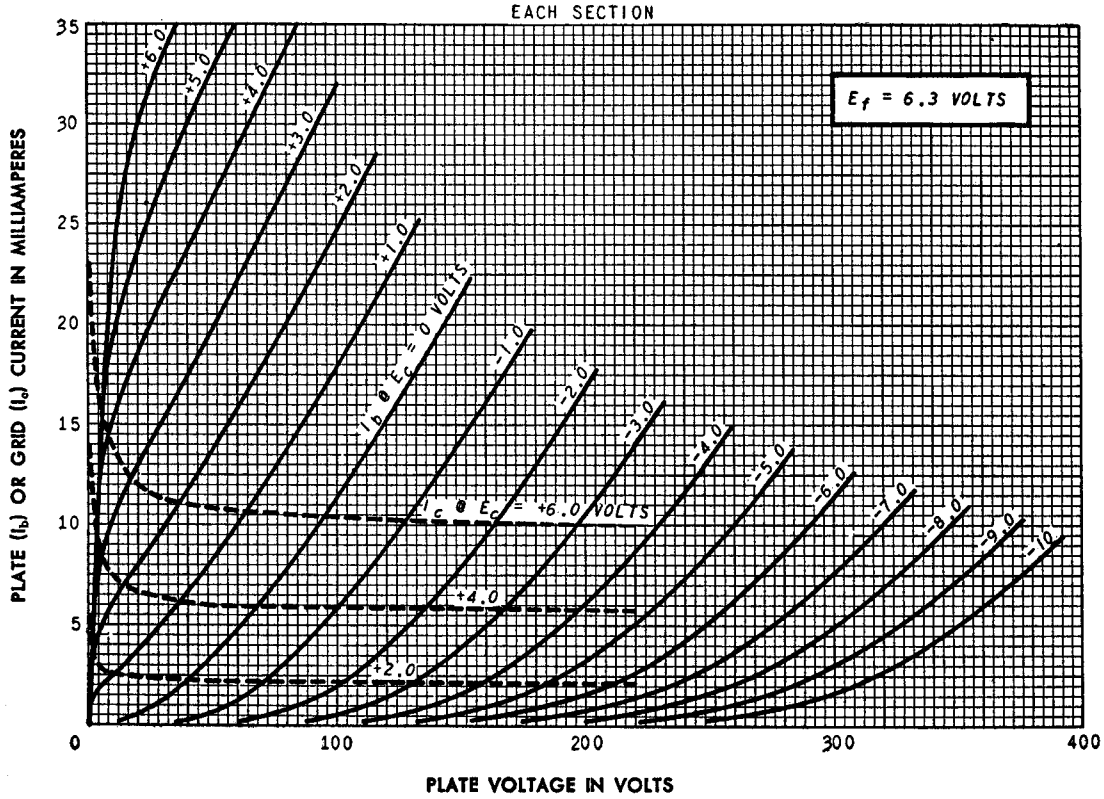
Stability Life Test
Statistical sample operated for one hour to evaluate and control initial variations in transconductance.

Survival Rate Life Test
Statistical sample operated for one hundred hours to evaluate and control early-life electrical and mechanical inoperatives.

Heater-Cycling Life Test
Statistical sample operated for 2000 cycles to evaluate and control heater-cathode defects. Conditions of test include Ef = 7.5 volts cycled for one minute on and one minute off, Eb = Ec = 0 volts, and Ehk = 135 volts with heater positive with respect to cathode.

Shock Rating—600 G
Statistical sample subjected to five impact accelerations of 600 G in each of four different positions. The accelerating forces are applied by the Navy-type, High Impact (flyweight) Shock Machine for Electronic Devices or its equivalent.

Fatigue Rating—2.5 G
Statistical sample subjected to vibrational acceleration of 2.5 G for 32 hours minimum in each of three different positions. The sinusoidal vibration is applied at a fixed frequency between 25 and 60 cycles per second.



Altitude Rating—60,000 Feet
Statistical sample subjected to pressure of 55 millimeters of mercury to evaluate and control arcing and corona.

Note: The conditions for some of the indicated tests have deliberately been selected to aggravate tube failures for test and evaluation purposes. In no sense should these conditions be interpreted as suitable circuit operating conditions.

In the design of military equipment employing this tube, reference should be made to the appropriate MIL-E-1C specification.

BEAM POWER AMPLIFIER

DESCRIPTION

The GL-5686 is a heater-cathode type miniature beam power amplifier designed for dependable operation under service conditions encountered in mobile and aircraft use. The tube is suitable for Class A audio power-amplifier service or for Class C radio-frequency power-amplifier service up to 160 megacycles. Multiple leads on the cathode and screen grid facilitate radio-frequency by-passing at high frequencies.

PENTODE

DESCRIPTION

The GL-5725 is a miniature, dual-control, radio-frequency pentode designed for dependable operation under conditions encountered in mobile and aircraft service. The control grid and the suppressor grid can be used as independent control elements. The tube is suitable for use in gated or gain-controlled amplifiers, and in delay or mixer circuits.

TWIN-DIODE

DESCRIPTION

The GL-5726 is a miniature double-diode designed for dependable operation under conditions encountered in mobile and aircraft service. The heaters for the two diode units are internally connected in series so that a heater failure makes both units inoperative and are designed to minimize the possibility of failure under severe intermittent on-off operation.

THYRATRON

DESCRIPTION

The GL-5727 is a miniature, four-electrode, inert-gas-filled thyratron with negative control characteristics which is suitable for use in relay and grid-controlled-rectifier applications. Operating characteristics of the tube include a high-control ratio essentially independent of temperature over a wide range, low grid-anode capacitance, and very low grid current. The GL-5727 is specially designed to assure dependable life and reliable service under the exacting conditions encountered in mobile and aircraft applications. Features include a high degree of mechanical strength and a heater-cathode construction designed to withstand many-thousand cycles of intermittent operation.

TWIN TRIODE

DESCRIPTION

The GL-5751 is a high-mu nine-pin miniature tube with two triode sections, each of which has an individual cathode connection. The heater may be connected for either series or parallel operation. Distinctive design features of this twin triode result in a sturdy vibration-resistant tube for industrial or other applications where dependable operation under rigorous service conditions is a necessity. It is also well adapted to intermittent service conditions. To provide a safety factor in cathode performance, the heater current is slightly higher than in conventional tubes of this type.

GL-5788

IGNITRON

DESCRIPTION AND RATING

The GL-5788 is a permanently sealed water-cooled rectifier ignitron similar in construction and rating to the GL-5555/FG-238-B. Special features are reliable operation at higher water temperature and lower water pressure drop, than is possible with that tube, and distinctive (larger diameter) ignitor terminals. These features make possible the use of economical water-to-air heat exchangers at higher ambient temperatures, than are possible with the other tube, the operation of six tube cooling jackets in series on normal water supply line pressures, and assure the user against premature ignitor failures caused by connecting the auxiliary anode lead to an ignitor terminal. The tube is designed for operation in 300, 600 and 900 volt d-c industrial rectifier circuits. The continuous average anode current rating is 200 amperes per tube in rectifiers rated up to 400 volts d-c.

DESCRIPTION AND RATING

PLIOTRON GL-5797

The GL-5797 is a subminiature semi-remote-cutoff pentode suitable for use as a radio-frequency amplifier at frequencies up to approximately 400 megacycles. The tube is designed to give reliable service and dependable life under conditions of shock, vibration, and high ambient temperature as encountered in aircraft service. The heater-cathode construction is designed to withstand many-thousand cycles of intermittent operation. The GL-5797 is especially suited for applications where the supply voltage for the heater, plate, and screen is approximately 26.5 volts.

DESCRIPTION AND RATING

PLIOTRON GL-5798

The GL-5798 is a subminiature medium-mu twin triode suitable for use as an oscillator-mixer at frequencies up to approximately 400 megacycles. The tube is designed to give reliable service and dependable life under conditions of shock, vibration, and high ambient temperature as encountered in aircraft service. The heater-cathode construction is designed to withstand many-thousand cycles of intermittent operation. The GL-5798 is especially suited for applications in which the supply voltage for the heater and plates is approximately 26.5 volts.

TWIN TRIODE

DESCRIPTION

The GL-5814 is a nine-pin miniature medium-mu tube with two triode sections with individual cathode connections. It is similar in electrical characteristics to the 12AU7 receiving tube. The GL-5814, however, incorporates distinctive mechanical design features, and increased heater current which provides a safety factor in cathode performance. These features combine to produce a sturdy shock-resistant tube and one which will give long life under conditions of intermittent operation.

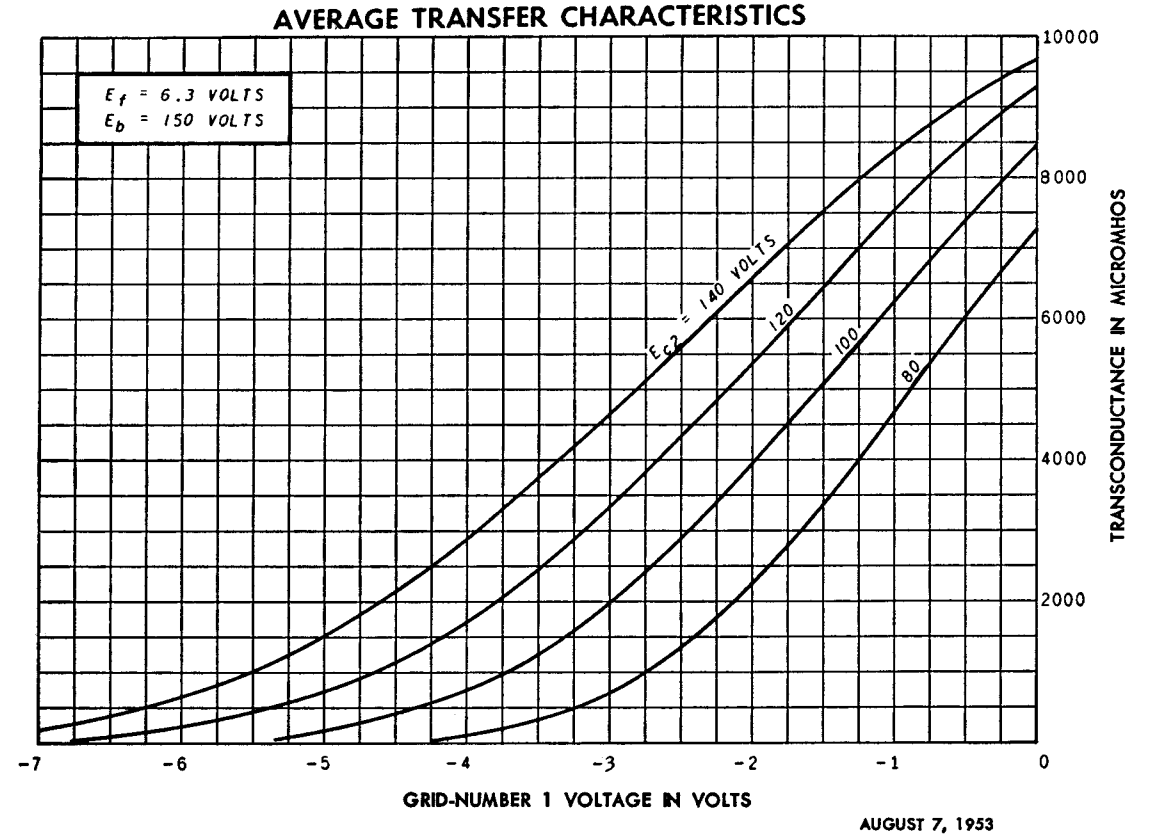
The indicated 500-hour values are life-test end points for the following conditions of operation: Ef = 6.3 volts, Eb = 100 volts, Ec2 = 100 volts, Rk = 150 ohms, Rg1 = 1.0 meg, Ehk = 200 volts with heater positive with respect to cathode, and bulb temperature = 220 C minimum.

SPECIAL TESTS AND RATINGS

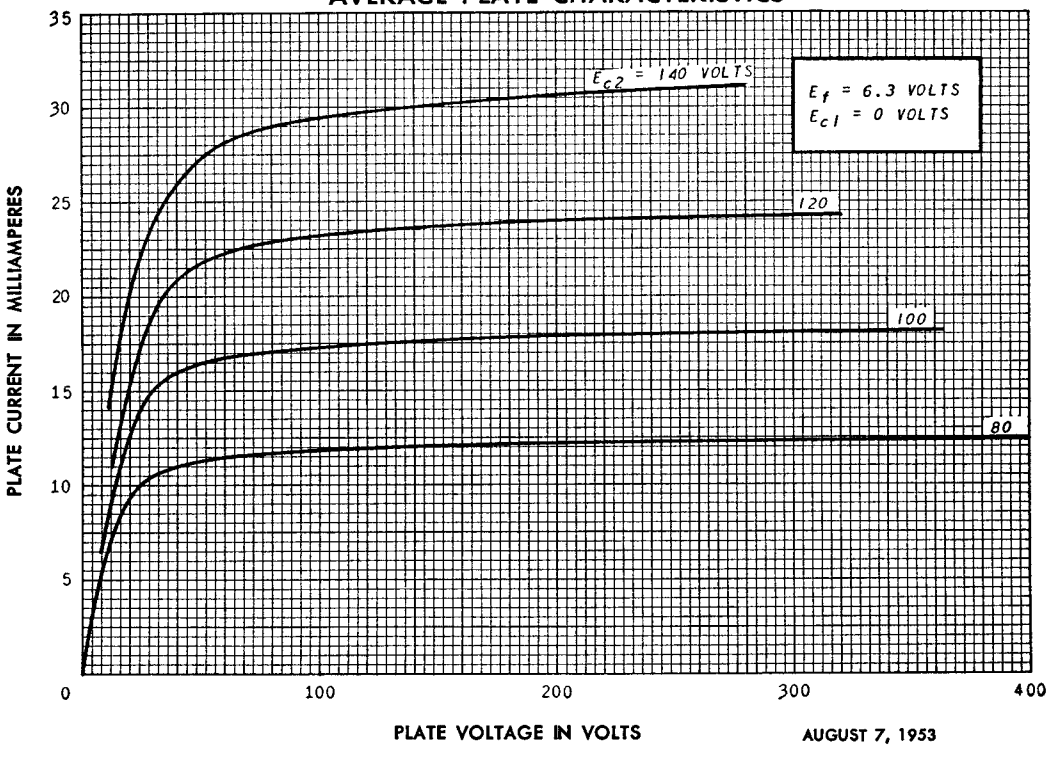
Stability Life Test
Statistical sample operated for one hour to evaluate and control initial variations in transconductance.

Survival Rate Life Test
Statistical sample operated for one hundred hours to evaluate and control early-life electrical and mechanical inoperatives.



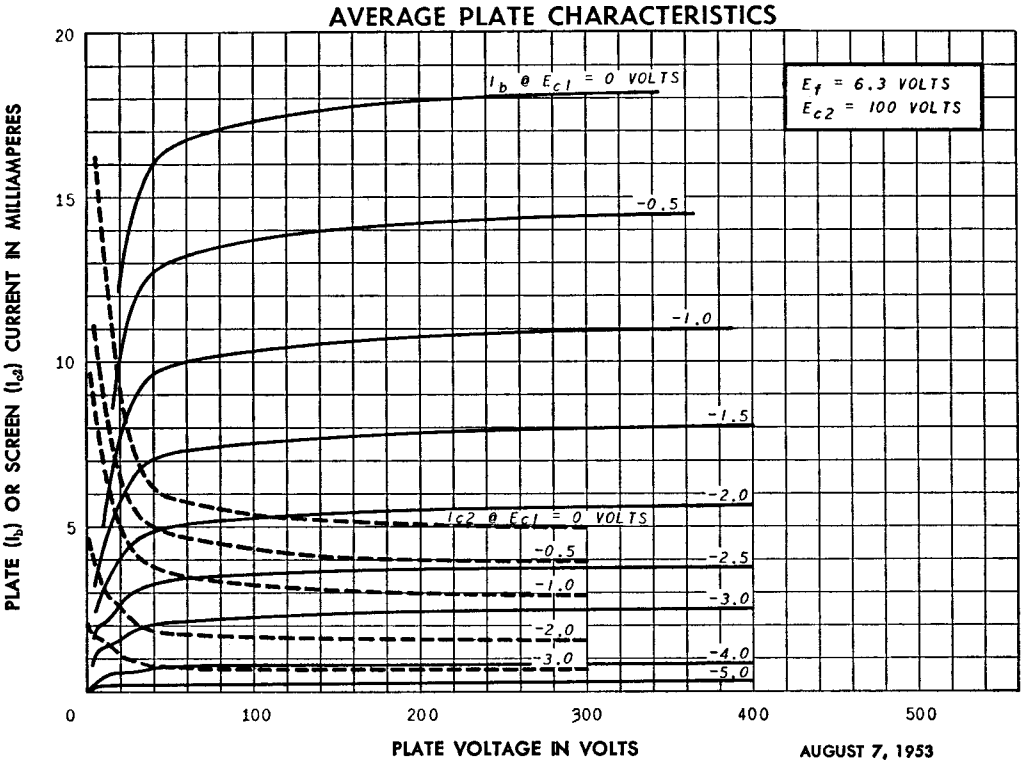
Heater-Cycling Life Test
Statistical sample operated for 2000 cycles to evaluate and control heater-cathode defects. Conditions of test include Ef = 7.0 volts cycled for one minute on and four minutes off, Eb = Ec2 = Ec1 = 0 volts, and Ehk = 140 volts RMS.

Shock Rating—450 G
Statistical sample subjected to five impact accelerations of 450 G in each of four different positions. The accelerating forces are applied by the Navy-type, High Impact (flyweight) Shock Machine for Electronic Devices or its equivalent.



Fatigue Rating—2.5 G
Statistical sample subjected to vibrational acceleration of 2.5 G for 32 hours minimum in each of three different positions. The sinusoidal vibration is applied at a fixed frequency between 25 and 60 cycles per second.

Altitude Rating—60,000 Feet
Statistical sample subjected to pressure of 55 millimeters of mercury to evaluate and control arcing and corona.



Note: The conditions for some of the indicated tests have deliberately been selected to aggravate tube failures for test and evaluation purposes. In no sense should these conditions be interpreted as suitable circuit operating conditions.
In the design of military equipment employing this tube, reference should be made to the appropriate MIL-E-1 specification.

DESCRIPTION AND RATING

PENTODE GL-5899

FIVE-STAR TUBE

★ ★ ★ ★ ★

The GL-5899 is a subminiature semi-remote-cutoff pentode intended for use as a wide-band, high-frequency amplifier. Its semi-remote-cutoff characteristic makes it suitable for use in circuits to which it is desired to apply automatic-gain-control. This tube is designed for service under severe conditions of mechanical shock and mechanical vibration, and where high ambient temperatures will be encountered. The tube is especially suited for compact military applications because of its dependable performance, stable operating characteristics, and small size.

The indicated 500-hour values are life-test end points for the following conditions of operation: Ef = 6.3 volts, Eb = 100 volts, Ec2 = 100 volts, Rk = 220 ohms, Rg1 = 0.47 meg, Ehk = 200 volts with heater positive with respect to cathode, and bulb temperature = 220 C minimum.

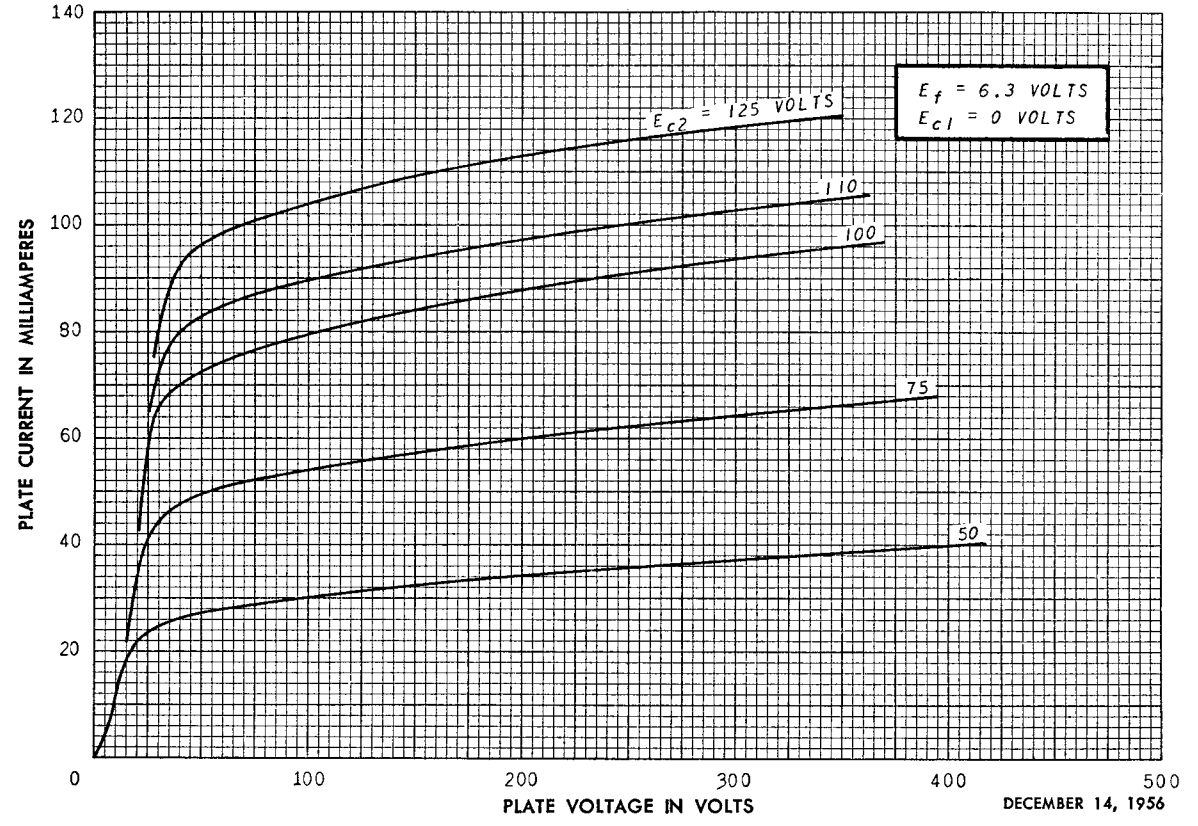
SPECIAL TESTS AND RATINGS

Stability Life Test
Statistical sample operated for one hour to evaluate and control initial variations in power output.

Survival Rate Life Test
Statistical sample operated for one hundred hours to evaluate and control early-life electrical and mechanical inoperatives.

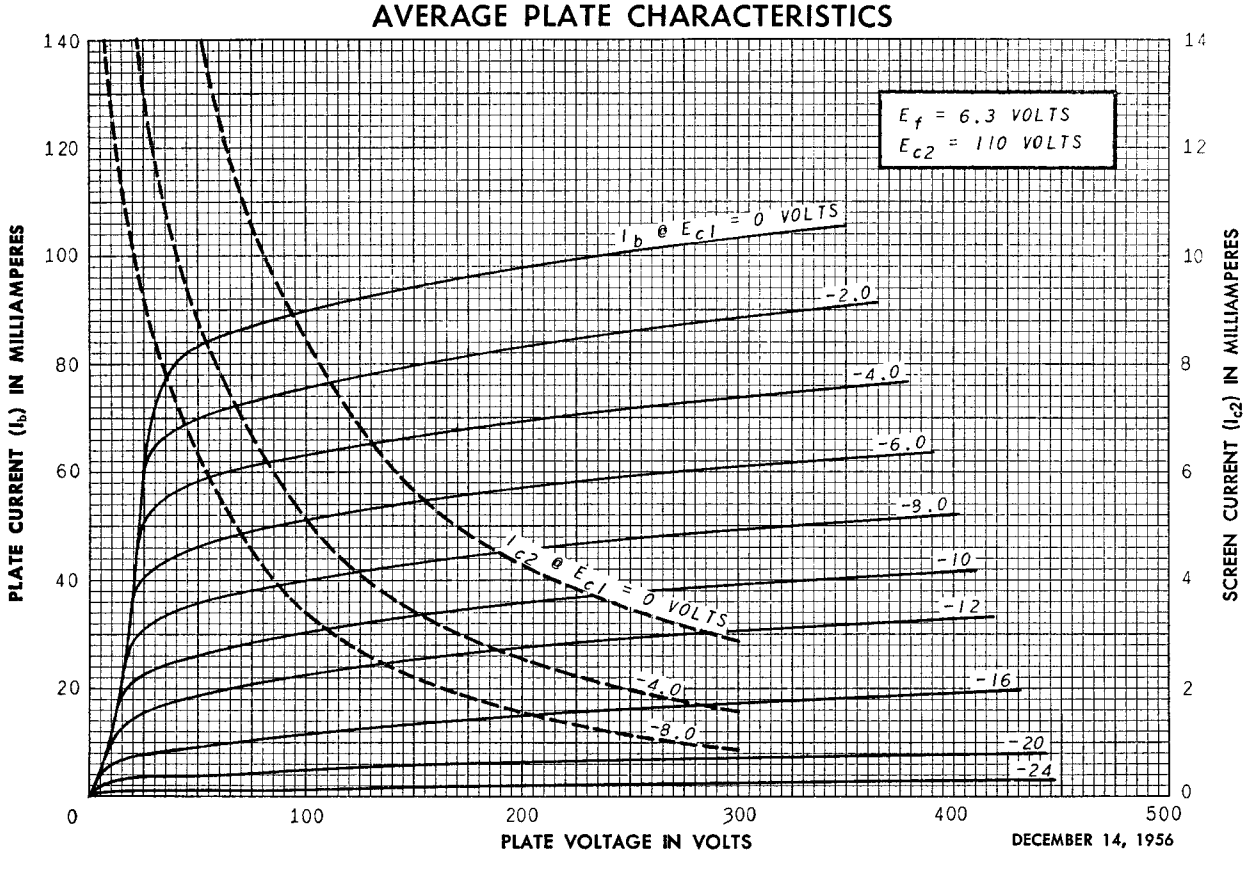
Heater-Cycling Life Test
Statistical sample operated for 2000 cycles minimum to evaluate and control heater-cathode defects. Conditions of test include Ef = 7.0 volts cycled for one minute on and four minutes off, Eb = Ec2 = Ec1 = 0 volts, and Ehk = 140 volts RMS.

Shock Rating—450 G
Statistical sample subjected to five impact accelerations of 450 G in each of four different positions. The accelerating forces are applied by the Navy-type, High Impact (flyweight) Shock Machine for Electronic Devices or its equivalent.



Fatigue Rating—2.5 G
Statistical sample subjected to vibrational acceleration of 25 G for 32 hours minimum in each of three different positions. The sinusoidal vibration is applied at a fixed frequency between 25 and 60 cycles per second.

Altitude Rating—60,000 Feet
Statistical sample subjected to pressure of 55 millimeters of mercury to evaluate and control arcing and corona.



Note: The conditions for some of the indicated tests have deliberately been selected to aggravate tube failures for test and evaluation purposes. In no sense should these conditions be interpreted as suitable circuit operating conditions.

In the design of military equipment employing this tube, reference should be made to the appropriate MIL-E-1 specification.

DESCRIPTION AND RATING

ION CHAMBER 5978

The 5978 is a high-pressure ion chamber for detecting gamma radiation. A distinctive design feature is the use of a grounded guard ring separated from the two electrodes by ceramic insulators having unusually high electrical resistance over a wide temperature range. The hermetically sealed envelope has ceramic-to-metal seals between the electrodes and insulators.

In operation the signal is taken from the central electrode, and the outer electrode, which is also the outside wall, is at the operating voltage.

BEAM POWER AMPLIFIER

DESCRIPTION

The GL-6005 is a miniature beam-power amplifier intended for use in medium-power audio-frequency applications. The tube is specially designed to assure dependable life and reliable service under the exacting conditions encountered in mobile and aircraft applications. Features include mechanical ruggedization and a heater-cathode construction designed to withstand many-thousand cycles of intermittent operation.

DESCRIPTION AND RATING

TRANSMITTING TUBE GL-6017

The GL-6017 is a three-electrode transmitting tube with a metal-and-ceramic envelope for use as a power amplifier or oscillator in Class B or Class C service for industrial or communications applications. This tube is designed particularly for grounded-grid operation.

The GL-6017 has an indirectly heated thoria-coated cathode, a plate dissipation of 1000 watts, and is forced-air cooled. Maximum ratings apply at frequencies up to 400 megacycles.

In Class C grounded-grid service this tube can deliver a peak power output of 1100 watts. In grounded-filament service the output is 900 watts.

The GL-6017 provides a compact triode for those applications which require the same power ratings as the four-electrode types GL-6019 and GL-6183, but where the higher frequencies at which these tubes are rated are not required.

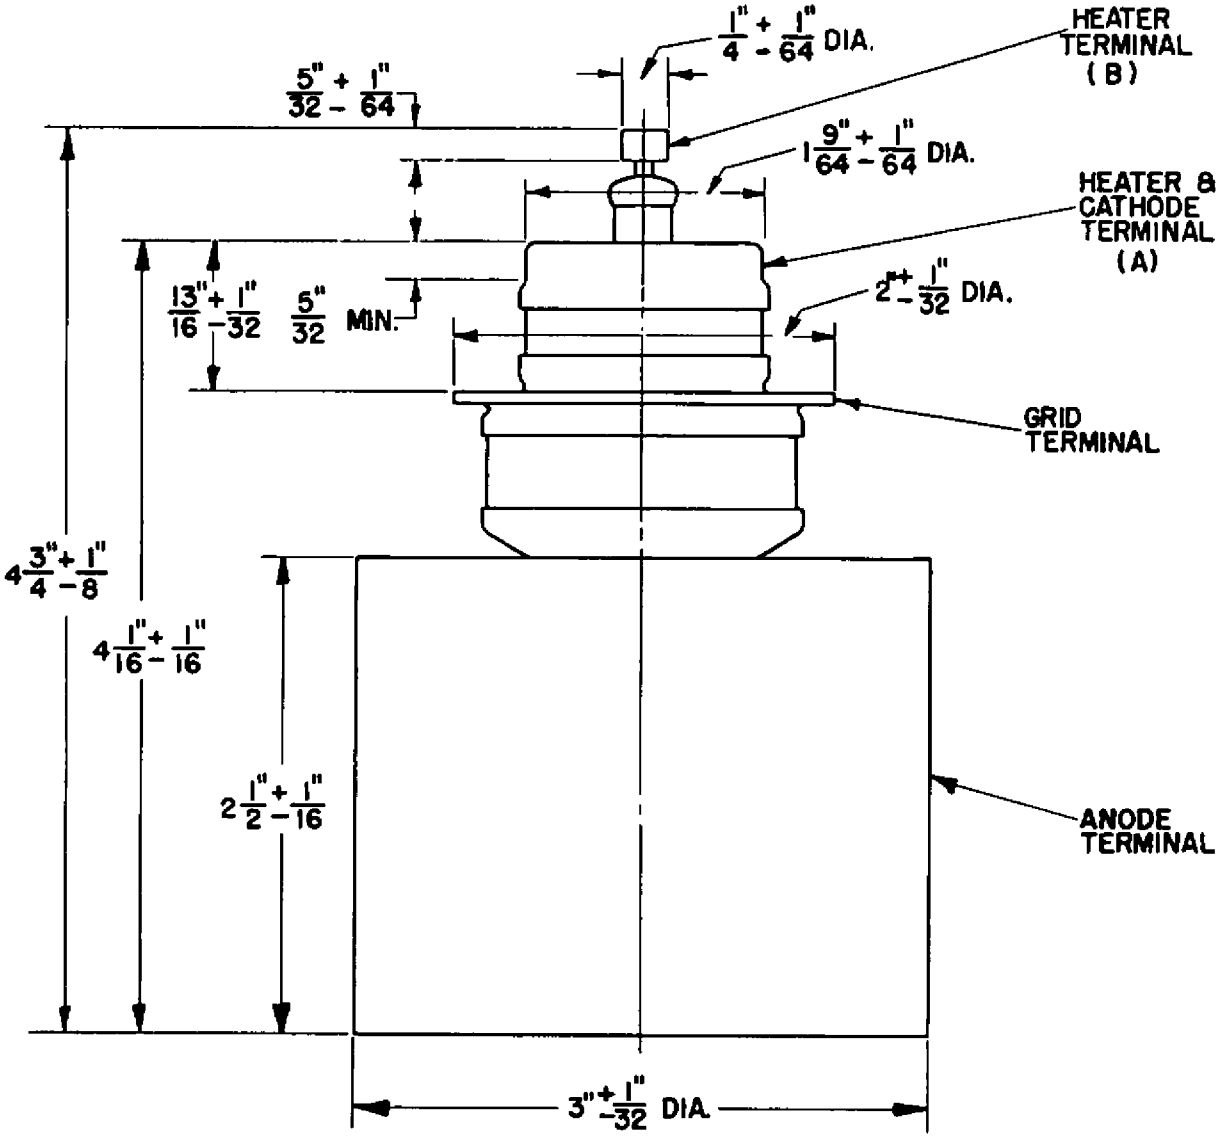
* Heater and cathode life can be conserved by operating the heater at the lowest voltage which will give the desired power output. The proper operating value may be found by reducing the heater voltage with normal modulation applied until a reduction in output is observed. The heater voltage must then be increased by an amount equivalent to the maximum percentage regulation of the heater voltage supply.

† Represents maximum useable cathode current (Plate current plus grid current for any condition of operation).



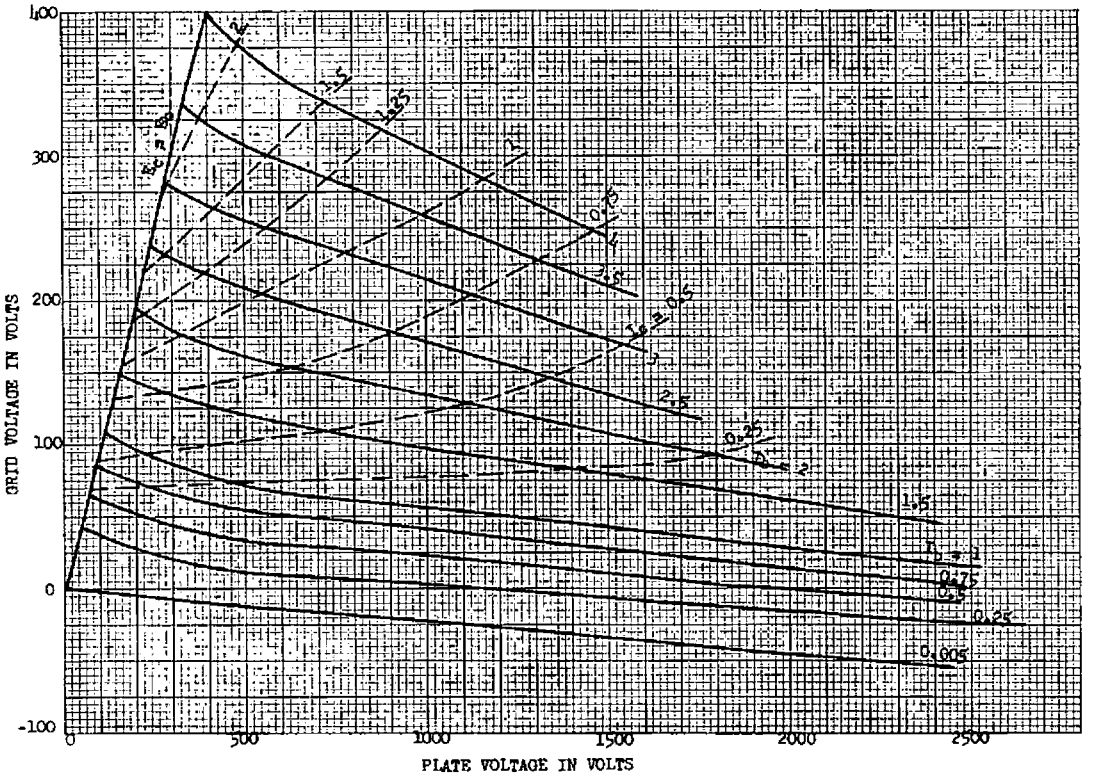
‡ Measured with a 6-inch outside diameter and 1 1/2-inch inside diameter flat shield connected to the grid terminal and grounded.

π At crest of audio-frequency cycle with modulation factor of 1.

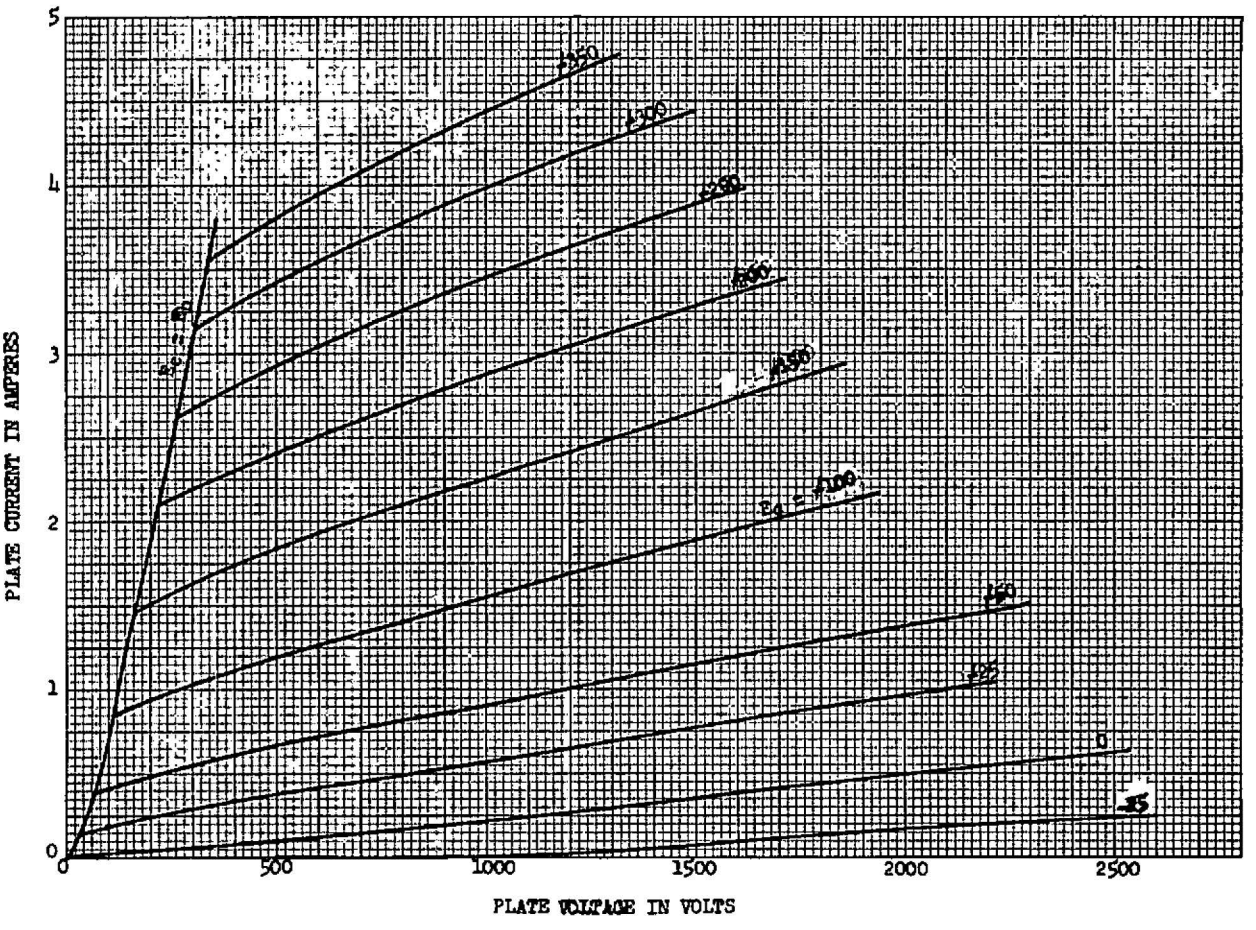
Δ Includes power transferred from driver stage.

◊ The carrier of the driver modulated 100 percent.

§ Modulation essentially negative may be used if the positive peak of the audio-frequency envelope does not exceed 115 percent of the carrier condition.



NOTES:



(A) MAXIMUM ECCENTRICITY 0.050" WITH RESPECT TO THE AXIS OF RADIATOR.

(B) MAXIMUM ECCENTRICITY 0.040" WITH RESPECT TO CENTERLINE DETERMINED BY THE CENTERS OF BOTTOM OF RADIATOR AND HEATER TERMINAL (A).

GL-6017
Average Plate Characteristics
E_f = 10 Volts A-c

GENERAL ELECTRIC

TUBE DEPARTMENT
SCHENECTADY, NEW YORK

DESCRIPTION AND RATING

TRANSMITTING TUBE GL-6019

The GL-6019 is a four-electrode transmitting tube featuring a metal-and-ceramic envelope designed for use as a power amplifier or oscillator in grounded-grid circuits with both grids maintained at radio-frequency ground potential. The output circuit is connected between the anode and the screen grid. The anode is capable of dissipating two kilowatts. Cooling is accomplished by water and forced air with the water jacket an integral part of the anode. The cathode is indirectly heated and thoria coated. Maximum ratings apply up to 900 megacycles.

When used as a Class B grounded-grid broadband television amplifier this tube has a useful synchronizing peak-power output of one kilowatt at 900 megacycles; in narrowband Class C service the output is one kilowatt of continuous power as an amplifier or oscillator. Because of its ratings, the GL-6019 is also well adapted to use in dielectric heating equipment.

The small size and close spacing of electrodes in the design of the tube combine with the ring-seal construction and the low-loss factor due to the gold-over-silver-plated external parts and the ceramic permit high operating efficiency. In addition, the grounded-grid construction eliminates the necessity for neutralization in a properly designed circuit. The small size of the GL-6019 permits compact mounting, and the integral water jacket and ring-seal construction allow quick plug-in installation.

TECHNICAL INFORMATION

GENERAL

Electrical Data	Minimum	Bogey	Maximum	
Heater Voltage*		6.3	6.8	Volts
Heater Current at Bogey Voltage		24		Amperes
Heater Starting Current			36	Amperes
Heater Cold Resistance		0.022		Ohm
Cathode Heating Time	1			Minutes

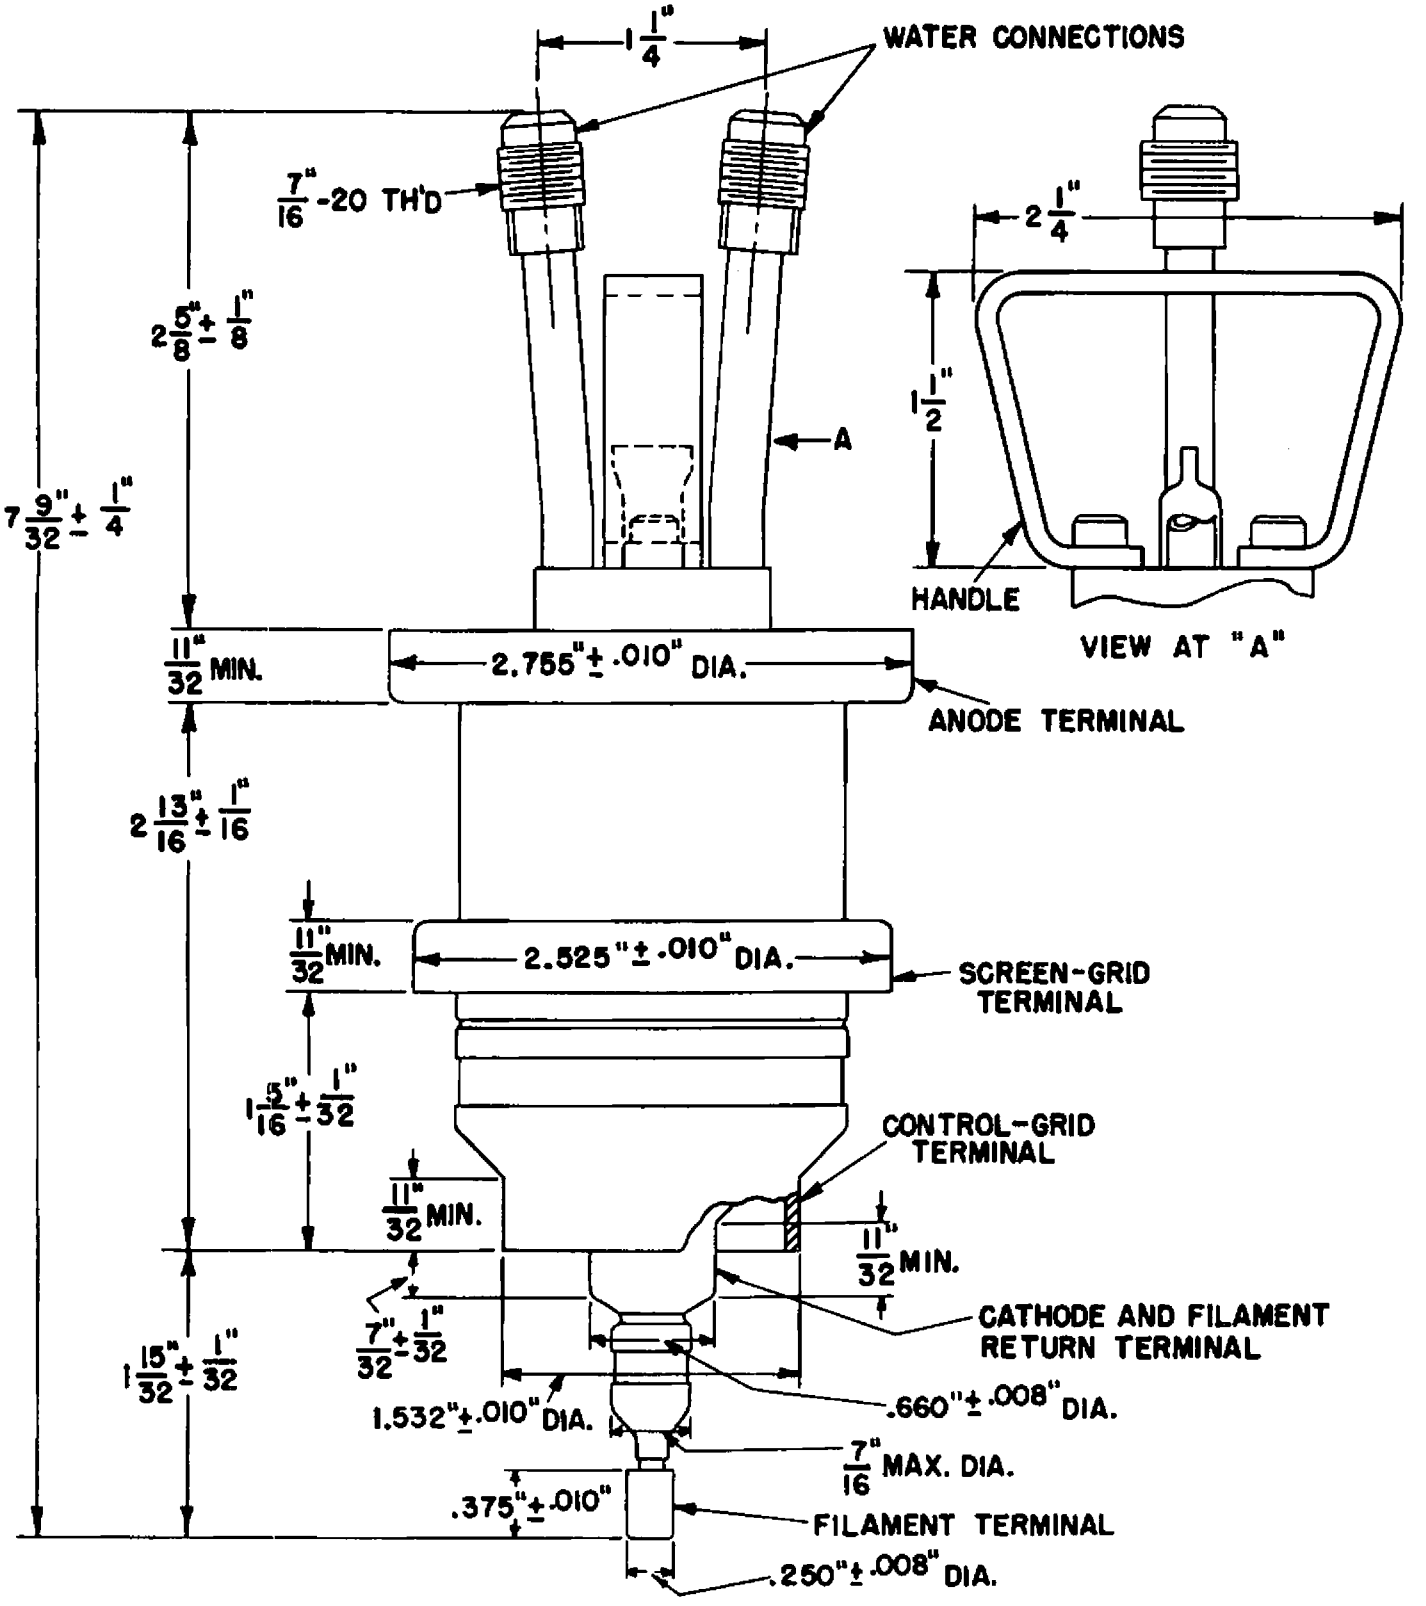
* The cathode of the GL-6019 in ultra-high-frequency service is subjected to considerable back bombardment, due to transit-time effects, which raises the temperature of the cathode. The amount of heating due to bombardment is a function of the operating conditions and frequency and must be compensated for by a reduction of the heater input to prevent overheating of the cathode with resulting short life. For long life, the GL-6019 should be put in operation with rated heater voltage. After the circuit is adjusted for proper tube operation, heater voltage is adjusted to a value slightly above that at which circuit performance is affected. At 900 megacycles with typical operating conditions the heater voltage can be reduced to approximately 5 volts. At lower frequencies, the reduction will be less. Minor circuit readjustment may be necessary after the above adjustment.

† Represents maximum usable cathode current (plate current plus current to each grid) for any condition of operation.

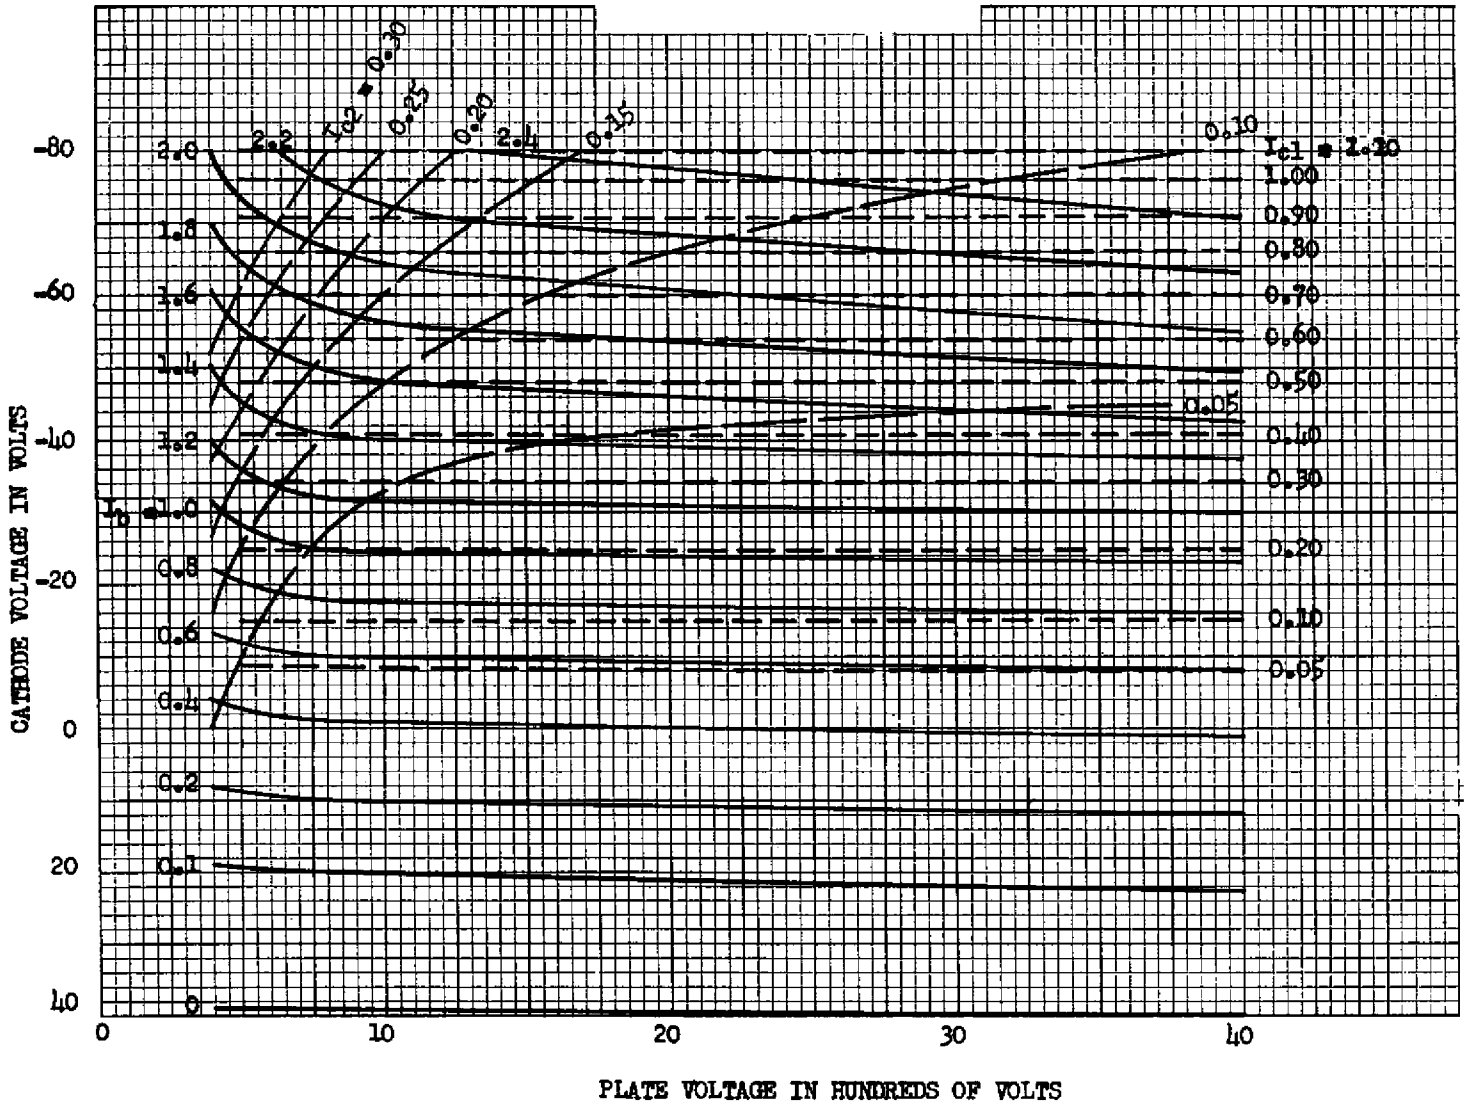


‡ Measured with a 6-inch diameter flat metal disk attached to the screen-grid ring. Control grid connected to the screen grid.

◊ Output capacitance measured between anode and screen grid. Control grid connected directly to screen grid.

π Useful power output including power transferred from driver stage.

Δ Modulation essentially negative may be used if the positive peak of the envelope does not exceed 115 percent of the carrier conditions.



\# Total anode power output including power transferred from driver stage.

DESCRIPTION AND RATING

The 6021 is a subminiature medium-mu twin triode for use in general-purpose amplifier applications. Each section has an individual cathode and is electrically independent.

The 6021 is a special-quality tube for use in critical industrial and military applications in which operational dependability is of primary importance. Features of the tube include a high degree of mechanical strength and a heater-cathode construction capable of withstanding many-thousand cycles of intermittent operation. When used in on-off control applications, the tube will maintain its emission capabilities after long periods of operation under cutoff conditions.

The indicated 500-hour values are life-test end points for the following conditions of operation for each section: Ef = 6.3 volts, Eb = 100 volts, Rk = 150 ohms, Rg = 1.0 meg, Ehk = 200 volts with heater positive with respect to cathode, and bulb temperature = 220 C minimum.

SPECIAL TESTS AND RATINGS

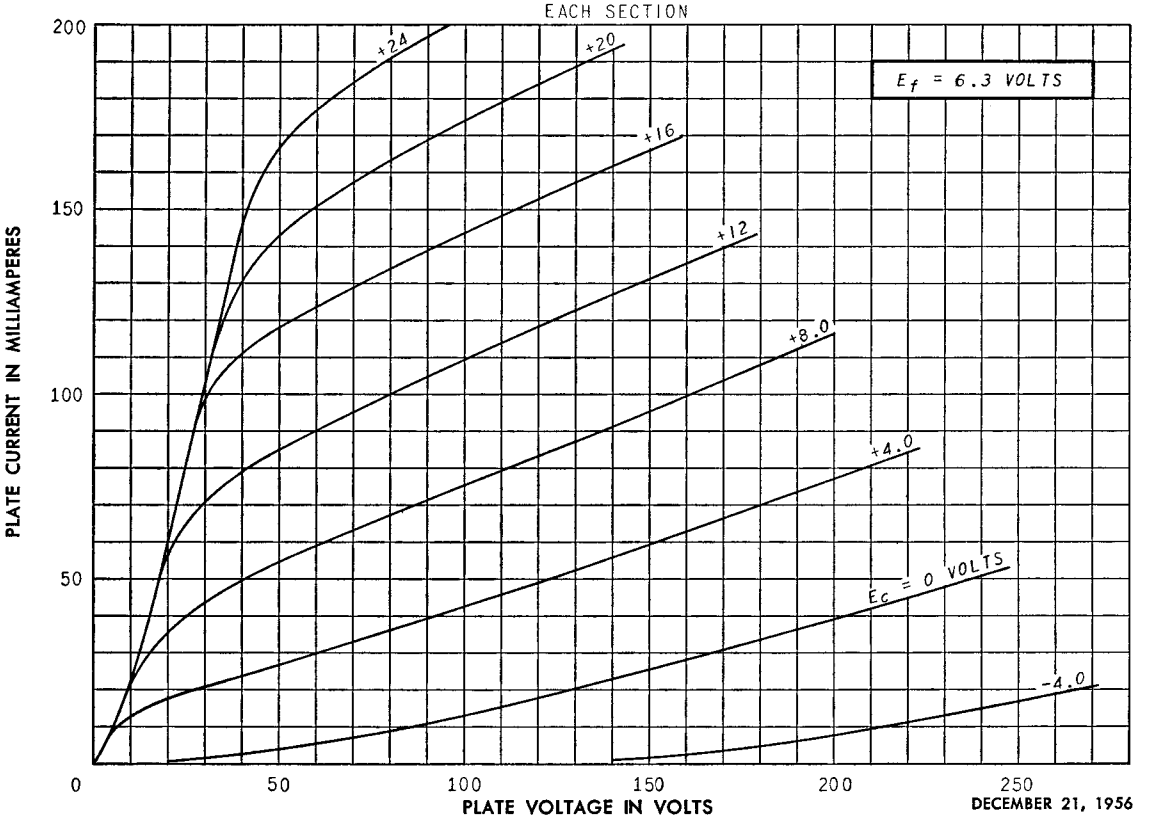
Stability Life Test
Statistical sample operated for one hour to evaluate and control initial variations in transconductance.

Survival Rate Life Test
Statistical sample operated for one hundred hours to evaluate and control early-life electrical and mechanical inoperatives.

Heater-Cycling Life Test
Statistical sample operated for 2000 cycles to evaluate and control heater-cathode defects. Conditions of test include Ef = 7.0 volts cycled for one minute on and four minutes off, Eb = Ec = 0 volts, and Ehk = 140 volts RMS.

Shock Rating—450 G
Statistical sample subjected to five impact accelerations of 450 G in each of four different positions. The accelerating forces are applied by the Navy-type, High Impact (flyweight) Shock Machine for Electronic Devices or its equivalent.

Fatigue Rating—2.5 G
Statistical sample subjected to vibrational acceleration of 2.5 G for 32 hours in each of three different positions. The sinusoidal vibration is applied at a fixed frequency between 25 and 60 cycles per second.



Altitude Rating—60,000 Feet
Statistical sample subjected to pressure of 55 millimeters of mercury to evaluate and control arcing and corona.

Note: The conditions for some of the indicated tests have deliberately been selected to aggravate tube failures for test and evaluation purposes. In no sense should these conditions be interpreted as suitable circuit operating conditions.

In the design of military equipment employing this tube, reference should be made to the appropriate MIL-E-1 specification.

DESCRIPTION AND RATING

TRANSMITTING TUBE 6039

The 6039 is a three-electrode tube designed for use as a grounded-grid class B radio-frequency amplifier and class C radio-frequency amplifier and oscillator in television and FM services. The anode is water-cooled and capable of dissipating 7 kilowatts. The cathode is a thoriated-tungsten filament. Maximum ratings apply up to 220 megacycles.

Utilizing the same general design principles that have proved so successful in the operation of the GL-9C24, this tube's predecessor, the 6039 has several features that enable it to give improved service over the older tube in both the television and FM bands. A material reduction in power cost results from use of a thoriated-tungsten filament which requires only 25.8 percent of the amount of power required. Higher output can be obtained - A pair of 6039's are capable of 10 kilowatts output in television service and 25 kilowatts in FM. Other features of the tube are low lead inductance, large terminal-contact areas, and silver-plated metal parts to reduce radio-frequency losses. In addition, neutralization is unnecessary in a properly designed circuit, and the problem of filament starting is eliminated since special precautions to limit the filament starting current are not required.

The 6039 can be substituted for the GL-9C24 with a saving of 74.2 percent in filament power providing modification of the filament circuit and minor mechanical changes are made.

DESCRIPTION AND RATING

THYRATRON 6044

The 6044 is a three-electrode, inert-gas-filled thyratron with negative control characteristic designed especially for motor-control circuits where short ionization time is required.

Satisfactory and dependable performance under conditions of shock and vibration is a particular advantage to be gained with the use of this tube. Utilizing a design where both electrical connection and mechanical support are provided by a single set of connections, the tube can be fastened to a control panel by means of the screws on the terminals. Because of this feature the tube can be held rigidly and securely in control apparatus, and the circuit design is simplified since sockets are unnecessary.

DESCRIPTION AND RATING

PLIOTRON GL-6046

The GL-6046 is a beam power amplifier intended for use in industrial applications which require relatively high plate currents at low plate and screen supply voltages. The GL-6046 is designed to maintain its emission capabilities after long periods of non-conduction. In addition the control grid is specially treated to minimize grid emission. The tube is electrically and physically a replacement for the 25L6-GT.

TWIN TRIODE

DESCRIPTION

The GL-6072 is a low-noise, low-microphonic miniature twin triode intended primarily for use in the low-level stages of high-gain audio-frequency amplifiers. The tube is specially designed to assure dependable life and reliable service under the exacting conditions encountered in mobile and aircraft applications. Additional features include mechanical ruggedization and a heater-cathode construction designed to withstand many thousand cycles of intermittent operation.

DESCRIPTION AND RATING

FULL-WAVE RECTIFIER GL-6087

FIVE-STAR TUBE

★ ★ ★ ★ ★

The GL-6087 is a full-wave high-vacuum rectifier for use in power supplies of moderate current requirements. The tube incorporates a unipotential cathode which is internally connected to the filament. The heating time of the tube, consequently, is approximately the same as that of other heater-cathode tubes in the equipment. This construction minimizes excessive surge voltages across the filter input capacitors during the warm-up period.

The GL-6087 is especially designed to assure dependable life and reliable service under the exacting conditions encountered in mobile and aircraft applications. Features include a high degree of mechanical strength, a heater-cathode construction designed to withstand many-thousand cycles of intermittent operation, and the ability to perform satisfactorily at altitudes as high as 60.000 feet. Within the limitations of its maximum ratings, the GL-6087 is a replacement for the 5Y3-GT.

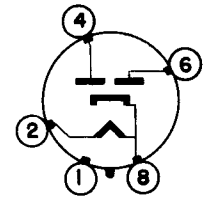
† To simplify the application of the maximum ratings to circuit design, the electrical design center maximum ratings are also presented in chart form as Rating Charts I, II, and III. Rating Chart I presents the maximum ratings for a-c plate-supply voltage and d-c output current. Rating Chart II provides a convenient method for checking conformance with the maximum steady-state peak-plate-current rating. Rating Chart III offers a convenient method for checking conformance with the maximum transient peak-plate-current rating.



With a capacitor-input filter, the conditions of each of Rating Charts I, II, and III must be satisfied in order to obtain performance within all of the electrical maximum ratings. With a choke-input filter, operation within the indicated boundary of Rating Chart I will assure performance within all of the appropriate electrical maximum ratings.

‡ The maximum ratings for a-c plate supply voltage and d-c output current are interrelated and are also dependent on whether a choke or capacitor-input filter is employed. This relationship is shown in Rating Chart I. With a capacitor-input filter, the operating point of d-c output current and a-c supply voltage must fall within the curve FAEDG. With a choke-input filter, the operating point must fall within the curve FABCDG.

§ Forces in any direction as applied by the Navy-type High Impact (flyweight) Shock Machine for Electronic Devices or its equivalent.

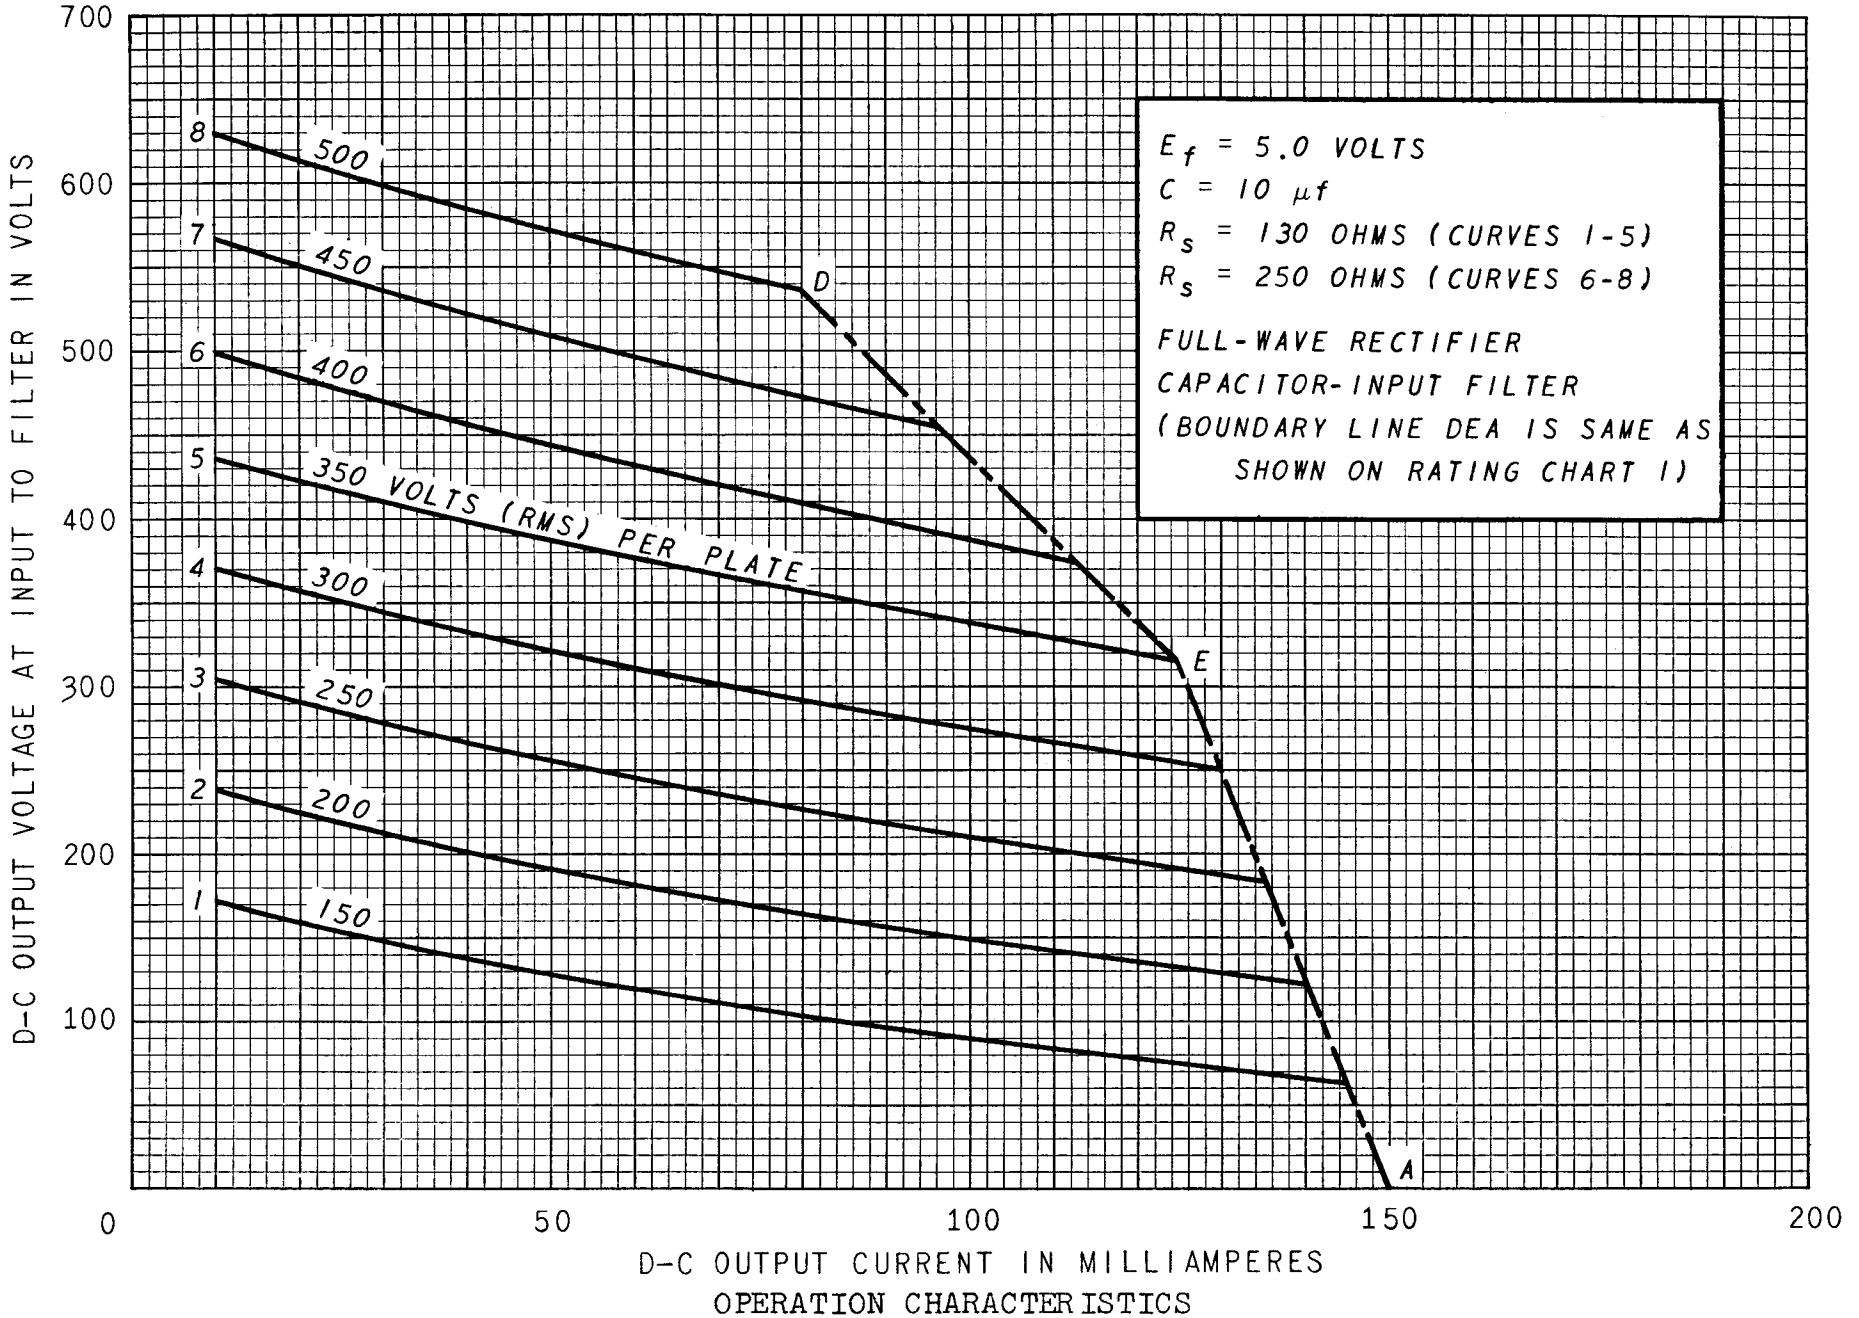
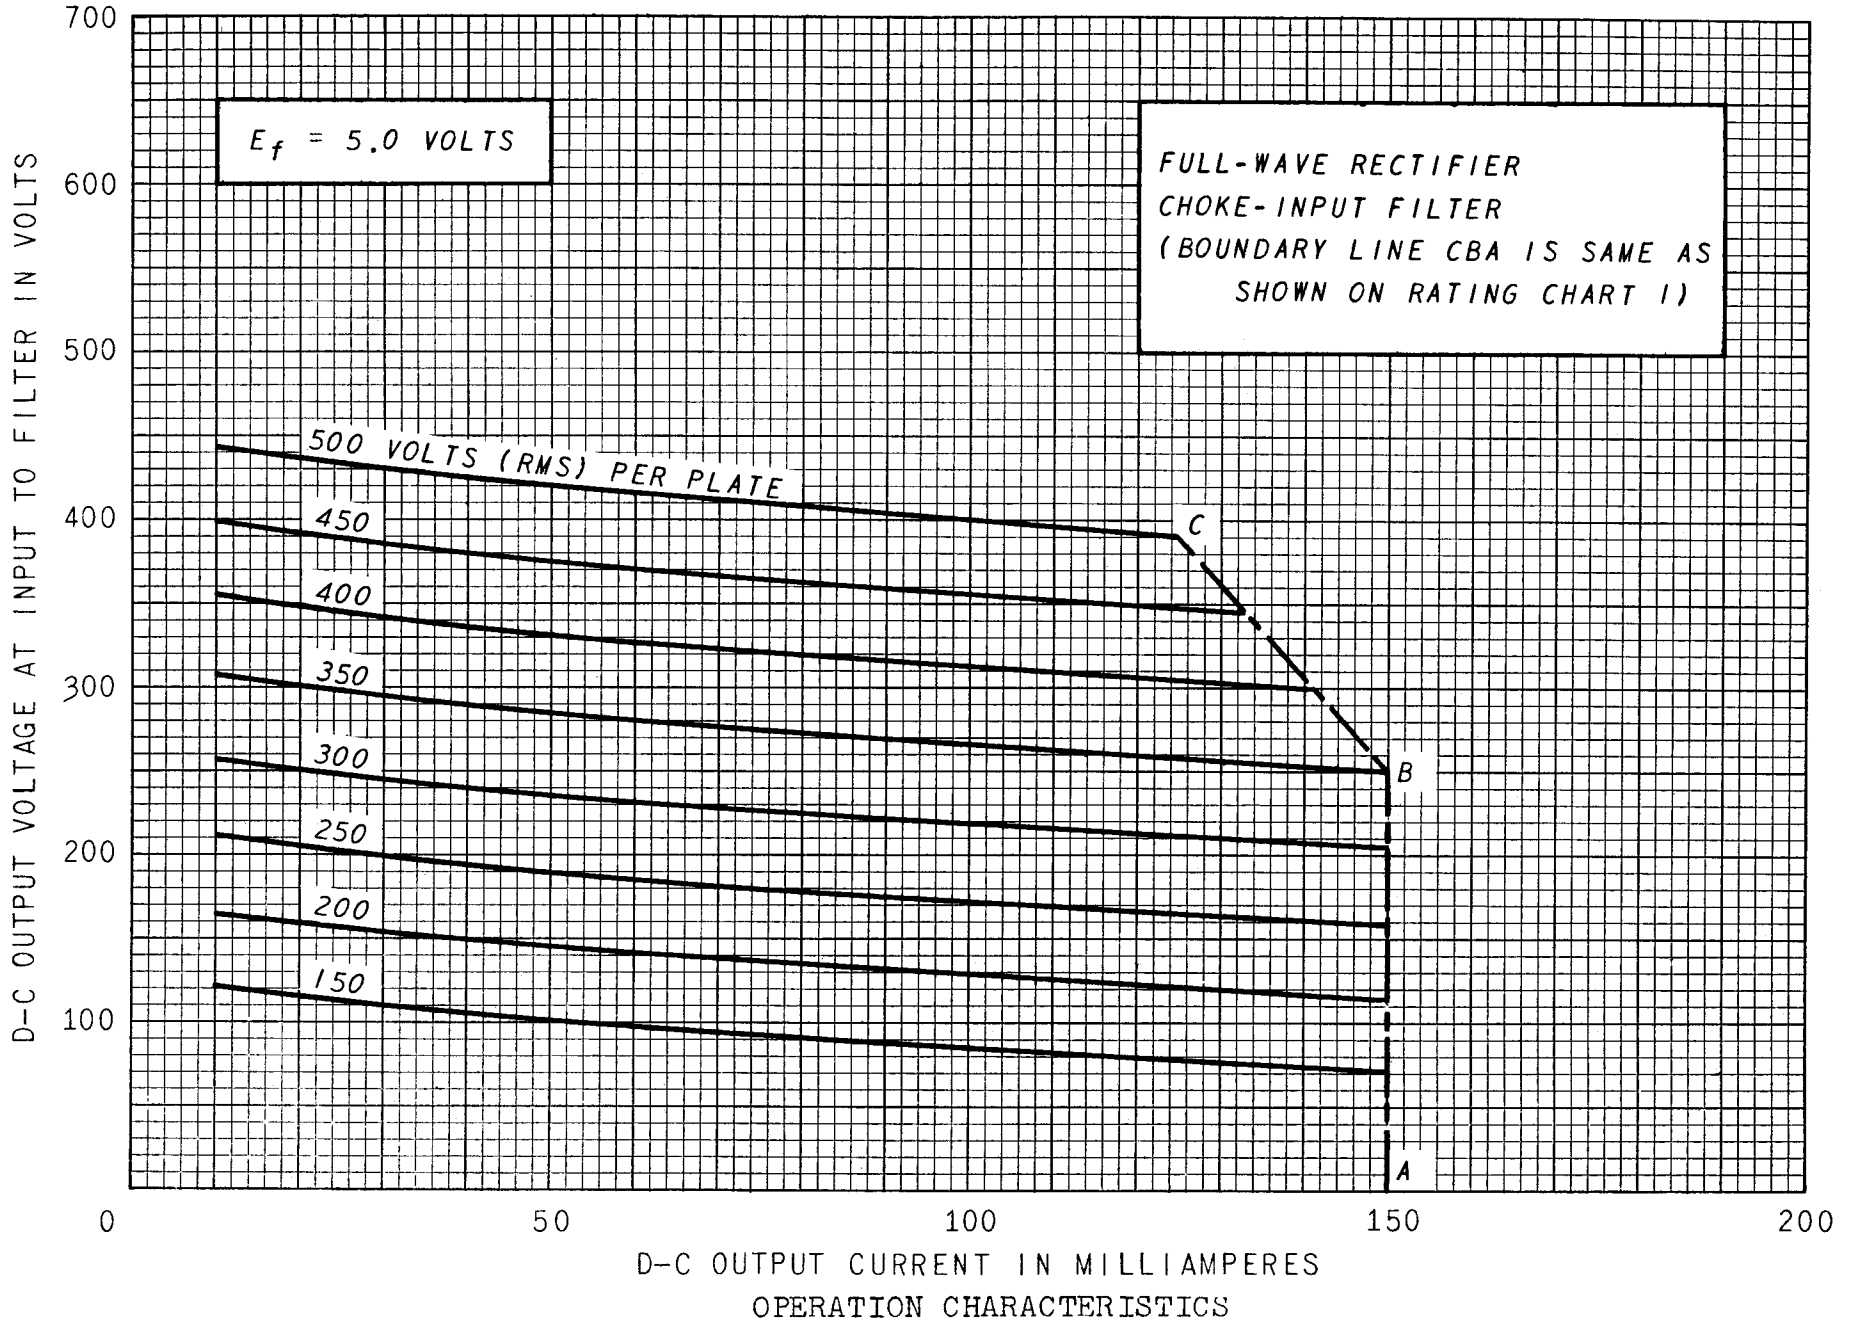
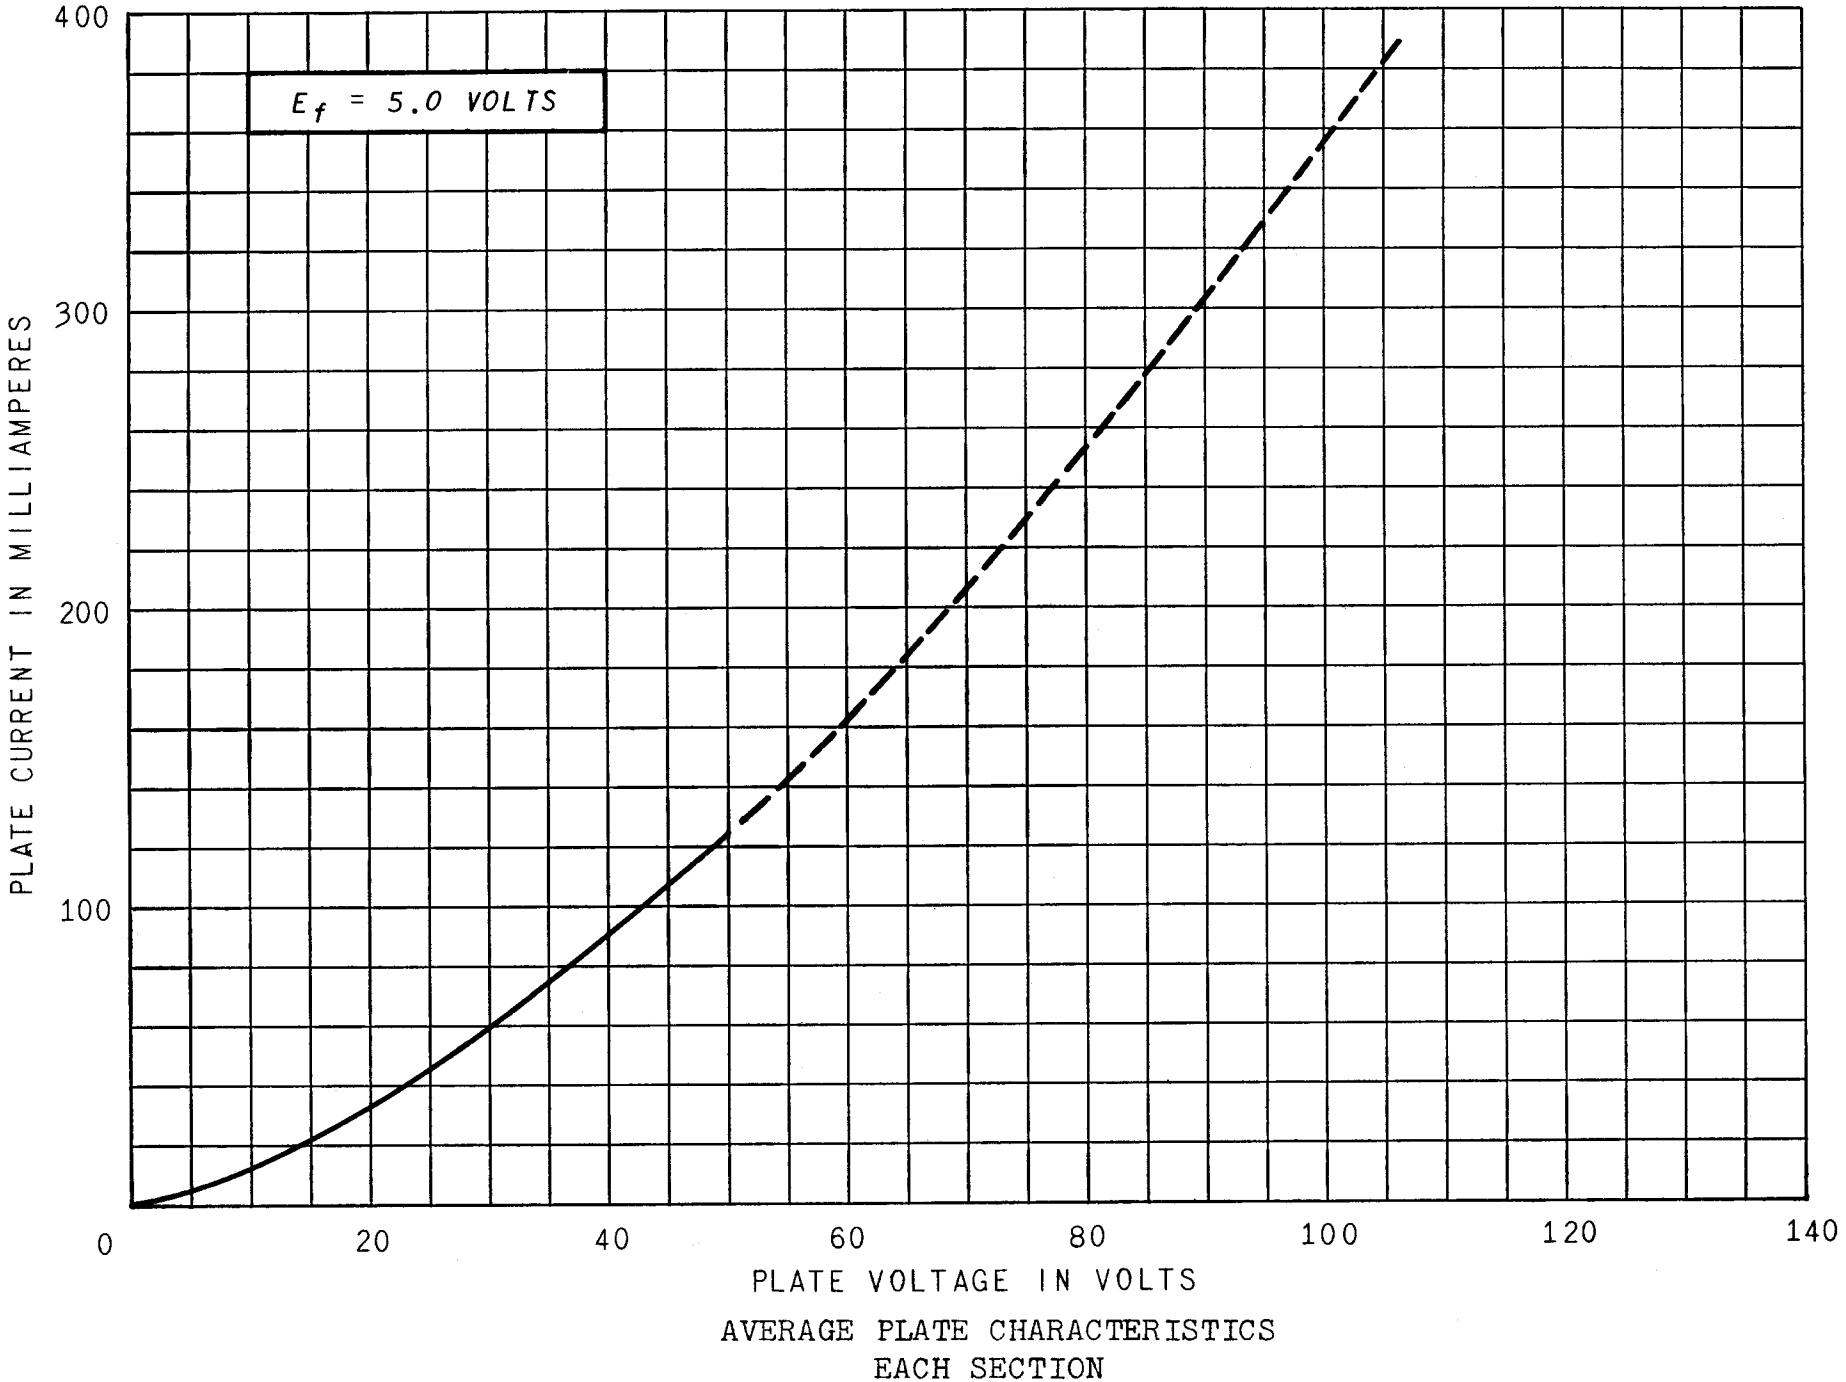
GL-6087



RATING CHART I



RATING CHART II



RATING CHART III

OPERATION CHARACTERISTICS

OPERATION CHARACTERISTICS

AVERAGE PLATE CHARACTERISTICS
EACH SECTION

The maximum ratings of high-vacuum rectifier tubes are based on inherent physical limitations of the tubes. Generally these ratings are expressed by the following quantities:

Maximum peak inverse plate voltage
Maximum a-c plate supply voltage (per plate)
Maximum steady-state peak plate current (per plate)
Maximum transient peak plate current (per plate)
Maximum d-c output current
Maximum heater-cathode voltage (cathode types only)

Although operation within the specified limits of these maximum ratings assures proper tube usage, the system involves some relatively difficult measurements and consequently imposes a considerable burden on the circuit designer.

To simplify the application of these maximum ratings to circuit design, a system of presenting rectifier ratings in the form of three rating charts has been developed. These rating charts, which are designated as Rating Charts I, II, and III, represent an alternate presentation of the maximum ratings and are applicable whenever the tube is used in a conventional rectifier circuit with an applied sinusoidal supply voltage.

Use of the rating charts requires only simple measurements of circuit characteristics with standard industrial meters. With a capacitor-input filter, proper tube usage requires that the operating characteristics satisfy the conditions of each of Rating Charts I, II, and III. With a choke-input filter, proper tube usage requires that the operating characteristics be within the prescribed area of permissible operation on Rating Chart I. In the case of heater-cathode types, the maximum heater-cathode-voltage rating is not covered by the rating charts, and attention must also be directed to this rating which is given as a numerical value on the Description and Rating sheet.

The ratings as presented in chart form are on the basis of the standard RTMA System of Design Center Maximums. In addition, the values of a-c supply voltage as presented refer to the unloaded supply voltages.

Rating Chart I

The maximum ratings for a-c plate supply voltage and d-c output current are interrelated and are also dependent on whether a choke- or capacitor-input filter is employed. This relationship is shown in Rating Chart I. As indicated on this chart, more lenient operation for one parameter permits the use of more severe operation for the other parameter.

To determine whether a given set of operating conditions is within the maximum ratings presented in Rating Chart I, the operating point of a-c supply voltage (RMS) per plate and d-c output current per plate for the application should be entered on the chart. If, for choke-input-filter operation, this point falls within the boundary FABCDG, operation within the ratings of a-c supply voltage and d-c output current is assured. For capacitor-input-filter operation, the operating point must fall within the boundary FAEDG.

If the operating point falls outside of the prescribed area of permissible operation, either the d-c output current or the a-c supply voltage must be reduced until operation within the area of permissible operation is obtained. The type of corrective action to be taken necessarily depends on the requirements of the application.

Rating Chart II

Rating Chart II represents a curve of maximum permissible rectification efficiency for capacitor-input-filter operation as a function of d-c output current. The purpose of this rating chart is to assure operation within the maximum steady-state peak-plate-current rating.

Rectification efficiency (η) is defined as follows:

$$\eta = \frac{\bar{E}}{\sqrt{2}\,Es} \tag{1}$$

where $\bar{E}$ = d-c output voltage at input to filter in volts
and E_s = RMS supply voltage per plate in volts.

To determine whether a given set of operating conditions is within the maximum ratings presented in Rating Chart II, the operating point of d-c output current per plate and rectification efficiency should be entered on the chart. If this point falls within the shaded area of the chart, operation within the maximum steady-state peak plate current is assured.

If the operating point falls outside of the prescribed area of permissible operation, corrective action must be taken. For a given a-c supply voltage and d-c output current, the rectification efficiency can usually be reduced either by increasing the total supply resistance per plate or by decreasing the filter input capacitor.

Rating Chart III

Rating Chart III presents a curve of minimum series plate supply resistance as a function of a-c supply voltage. The purpose of this chart is to assure operation within the maximum transient peak-plate-current rating. The transient peak plate current is often referred to as the hot-switching current.

Hot switching can occur in capacitor-input-filter circuits if the equipment is switched off and then switched on again before the temperature of the rectifier tube cathode has decreased appreciably. If during the off period the filter capacitor has discharged, a large transient current will flow at the time the supply voltage is reapplied. The largest transient current will occur when the supply voltage is at its peak amplitude at the instant it is reapplied to the circuit.

When the supply voltage is reapplied, the resulting transient current is limited only by the resistance offered by the tube and any resistance which might be in the circuit. Unless sufficient resistance is available to limit the transient current to the rated maximum value, excessive currents can flow which will destroy the rectifier tube. The minimum series plate supply resistance per plate (Rs) which is required to maintain the hot-switching current to its rated maximum value can be expressed as

$$Rs = \frac{\sqrt{2}\,Es - \hat{e}_{d(surge)}}{\hat{I}_{surge}} \tag{2}$$

where Es = RMS supply voltage per plate in volts,
$\hat{I}_{surge}$ = Maximum transient peak plate current per plate,
and $\hat{e}_{d(surge)}$ = Tube voltage drop in volts corresponding to $\hat{I}_{surge}$.

This equation forms the basis of Rating Chart III.

The minimum series-plate-supply resistance per plate is defined as consisting of the following components.

$$Rs = Rsec + N^2\,Rprim + Ra \tag{3}$$

where Rsec = d-c resistance of transformer secondary per section,
Rprim = d-c resistance of transformer primary,
Ra = d-c resistance of added series resistance per plate,
and N = Transformer voltage step-up ratio per section.

Series inductance in the plate supply is also effective in limiting the transient peak plate current. If appreciable series inductance is present in the plate supply, a smaller-than-indicated value of series-plate-supply resistance may be used providing it is determined experimentally that the combined effect of the available supply resistance and inductance is adequate to limit the transient peak plate current to its rated maximum value.

To determine whether a given set of operating conditions is within the maximum ratings presented in Rating Chart III, the total Rs is first calculated from measurements of Rpri, Rsec, Ra, and N. The operating point of Rs and a-c supply voltage is then entered on Rating Chart III. If the total plate-supply resistance is equal to or greater than the minimum value of Rs, as indicated by the curve, operation within the maximum transient peak-plate-current rating is assured. If the conditions of Rating Chart III are not satisfied, additional resistance should be added in series with each diode plate so that the indicated minimum value of Rs is obtained.

It should be noted that the plate-supply resistance serves to limit both the steady-state peak current and the transient peak current. The minimum value of resistance required for these two functions will not necessarily be the same. The larger value of resistance must be used.

Typical Example

To illustrate the use of the rating charts, consider the following example.

Problem:

A full-wave rectifier circuit employing a GL-6087 is operated with an 800-volt center-tapped transformer from a 117-volt supply. The input filter capacitor is 8 microfarads. Determine if the operation of the rectifier tube is within its maximum ratings.

Procedure:

The following measurements are made with the circuit operating:

Total D-c Output Current = 110 milliamperes
D-c Output Voltage at Filter Input, $\bar{E}$ = 410 volts

The following measurements are made with the tube removed from its socket:

RMS Transformer Primary Voltage, E_{pri} = 117 volts RMS
RMS Transformer Secondary Voltage per Plate, E_s = 400 volts RMS

The following measurements are made with the supply voltage removed:

D-c Resistance of the Transformer Primary, R_{pri} = 2.4 ohms
D-c Resistance of the Transformer Secondary per Section, R_{sec} = 88 ohms

Reference is next made to the published rating charts for the GL-6087.

Rating Chart I

A-c Plate Supply Voltage per Plate (RMS) = 400 volts.
D-c Output Current per Plate = $\frac{110}{2}$ = 55 milliamperes.

The point having as coordinates 400 volts and 55 milliamperes is entered on Rating Chart I. As this point is within the area indicated for capacitor-input filter, the conditions of Rating Chart I are satisfied.

Rating Chart II

Rectification Efficiency, η, is calculated from Equation (1).

$$\eta = \frac{\bar{E}}{\sqrt{2}\, E_s} \qquad (1)$$

$\bar{E}$ = 410 volts
E_s = 400 volts

$$\eta = \frac{410}{1.414\ (400)} = 0.725$$

D-c Output Current per Plate = 55 milliamperes

The point having as coordinates 0.725 and 55 milliamperes is entered on Rating Chart II. As this point is not within the area of permissible operation, the conditions of Rating Chart II are not satisfied. Before corrective action is taken, however, conformance with Rating Chart III will be examined.

Rating Chart III

The supply resistance per plate, R_s, is calculated from Equation (3).

$$R_s = R_{sec} + N^2 R_{prim} + R_a \qquad (3)$$

$$N = \frac{400 \text{ volts RMS}}{117 \text{ volts RMS}} = 3.42$$

$N^2 = 11.7$

$R_{sec} = 88$ ohms

$R_{prim} = 2.4$ ohms

$R_a = 0$ ohms

$$R_s = 88 + 11.7\ (2.4) + 0$$

$R_s = 116$ ohms

A-c Plate Supply Voltage per Plate (RMS) = 400 volts

The point having as coordinates 116 ohms and 400 volts is entered on Rating Chart III. As 116 ohms is less than the required minimum value of 165 ohms, the conditions of Rating Chart III are not satisfied. Corrective action is therefore required both for the conditions of Rating Charts II and III.

Corrective Action

The corrective action may take any of several forms. Assume, for the present example, that it is decided to add a resistor in series with each plate.

From Rating Chart III, the minimum value of R_s required for a 400 volt supply is 165 ohms. Therefore, a 56-ohm resistor should be added in series with each plate so that R_s will be increased from 116 ohms to a value greater than the required 165 ohms.

With a 56-ohm resistor added to each plate, the d-c output voltage and current are again measured and found to be 395 volts and 110 milliamperes. The three Rating Charts are again checked for conformity, but now using $\eta = 0.698$ and Rs = 172 ohms. The conditions of all three rating charts are now satisfied, and proper tube usage is assured.

The chief advantage of the rating chart method for checking tube operation is that only simple measurements need be made. These include the d-c measurement of output current, output voltage, several resistances, and the a-c measurements of supply voltage and transformer voltage step-up ratio.

The information contained in the rating charts can also be used to advantage in the initial design of the rectifier circuit. When used in conjunction with the published regulation curves, conformity of performance to the maximum ratings can be predicted to a good degree of accuracy.

DESCRIPTION AND RATING

The 6111 is a subminiature medium-mu twin triode for use in general-purpose amplifier applications. Each section has an individual cathode and is electrically independent. The tube may also be used as a combined oscillator and mixer in high-frequency circuits.

The 6111 is a special-quality tube intended for use in critical industrial and military applications in which operational dependability is of primary importance. Features of the tube include a high degree of mechanical strength and a heater-cathode construction capable of withstanding many-thousand cycles of intermittent operation. When used in on-off control applications, the tube will maintain its emission capabilities after long periods of operation under cutoff conditions.

SPECIAL TESTS AND RATINGS

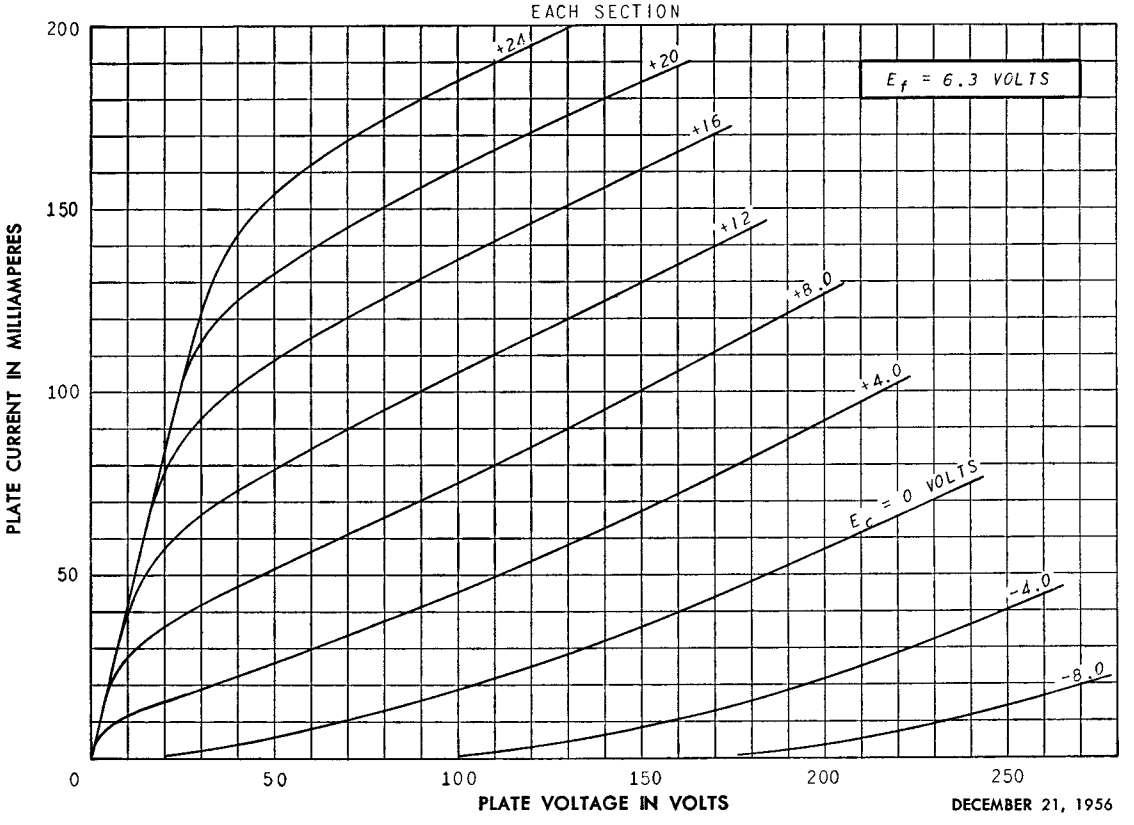
Stability Life Test
Statistical sample operated for one hour to evaluate and control initial variations in transconductance.

Survival Rate Life Test
Statistical sample operated for one hundred hours to evaluate and control early-life electrical and mechanical inoperatives.

Heater-Cycling Life Test
Statistical sample operated for 2000 cycles to evaluate and control heater-cathode defects. Conditions of test include Ef = 7.0 volts cycled for one minute on and four minutes off, Eb = Ec = 0 volts, and Ehk = 140 volts RMS.

Shock Rating—450 G
Statistical sample subjected to five impact accelerations of 450 G in each of four different positions. The accelerating forces are applied by the Navy-type, High Impact (flyweight) Shock Machine for Electronic Devices or its equivalent.

Fatigue Rating—2.5 G
Statistical sample subjected to vibrational acceleration of 2.5 G for 32 hours in each of three different positions. The sinusoidal vibration is applied at a fixed frequency between 25 and 60 cycles per second.



Altitude Rating—60,000 Feet
Statistical sample subjected to pressure of 55 millimeters of mercury to evaluate and control arcing and corona.

Note: The conditions for some of the indicated tests have deliberately been selected to aggravate tube failures for test and evaluation purposes. In no sense should these conditions be interpreted as suitable circuit operating conditions.

In the design of military equipment employing this tube, reference should be made to the appropriate MIL-E-1 specification.

DESCRIPTION AND RATING

PENTODE GL-6134

FIVE-STAR TUBE

★★★★★

The GL-6134 is a sharp-cutoff pentode intended for service as a wide-band radio-frequency or intermediate-frequency amplifier or as a video-amplifier. The tube is specially designed to assure dependable life and reliable service under the exacting conditions encountered in mobile and aircraft applications. Features include a high degree of mechanical strength and a heater-cathode construction designed to withstand many-thousand cycles of intermittent operation. Electrically and physically, the GL-6134 is a replacement for the 6AC7.

TRIODE

DESCRIPTION

The GL-6135 is a miniature medium-mu triode designed for use as a local oscillator in very-high-frequency receivers. It is also suitable for use as an audio amplifier and for use in general-purpose applications. The GL-6135 is specifically designed to assure dependable life and reliable service under the exacting conditions encountered in mobile and aircraft applications. Features include a high degree of mechanical strength, a heater-cathode construction designed to withstand many-thousand cycles of intermittent operation, and a relatively high value of plate-to-grid insulation resistance throughout life.

Beam Pentode

6146-A

FOR POWER AMPLIFIER, OSCILLATOR, AND MODULATOR APPLICATIONS

HIGH POWER SENSITIVITY

90 WATTS CW INPUT (ICAS) UP TO 60 MC

T-12 BULB

OCTAL 8-PIN BASE

The 6146-A is a beam pentode designed for use as a radio-frequency power amplifier and oscillator or as an audio-frequency power amplifier and modulator in mobile or fixed equipment. Featuring high power sensitivity the 6146-A may be operated with full input up to 60 megacycles and with reduced input to 175 megacycles.

The 6146-A incorporates triple-base-pin connections for the cathode and beam plates to permit effective r-f grounding, and an octal base with a metal sleeve having its own base-pin terminal. The sleeve, which shields the input to the tube and isolates it from the output circuit, eliminates the necessity for external shielding.

NOTES

★ The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

● Heater current of a bogey tube at Ef 6.3 volts.

♦ Continuous Commercial Service

□ Intermittent Commercial and Amateur Service

▲ Obtained preferably from a separate source or from the plate voltage with a voltage divider.

§ Measured without external shield.

⊕ Driver stage should be capable of supplying the specified driving power at low distortion to the number 1 grids of the AB2 stage. To minimize distortion, the effective resistance per grid number 1 circuit of the AB2 stage should be held at low value. For this purpose the use of transformer coupling is recommended. In no case, however, should the total dc grid number 1 circuit resistance exceed 30,000 ohms when the tube is operated at maximum ratings. For operation at less than maximum ratings, the dc grid number 1 circuit resistance may be as high as 100,000 ohms.

† Obtained preferably from a separate source modulated with the plate supply, or from the modulated plate supply through a series resistor.

‡ Obtained from grid number 1 resistor or from a combination of grid number 1 resistor with either fixed supply or cathode resistor.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

DESCRIPTION AND RATING

TRANSMITTING TUBE GL-6183

The GL-6183 is a four-electrode transmitting tube featuring a metal-and-ceramic envelope designed for use as a power amplifier or oscillator in grounded-grid circuits with both grids maintained at radio-frequency ground potential. The output circuit is connected between the anode and the screen grid. The anode is capable of dissipating one and one-half kilowatts. Cooling is accomplished by forced air with the radiator an integral part of the anode. The cathode is indirectly heated and thoria coated. Maximum ratings apply up to 900 megacycles.

When used as a Class B grounded-grid broadband television amplifier this tube has a useful synchronizing peak-power output of one kilowatt at 900 megacycles; in narrow band Class C service the output is one kilowatt of continuous power as an amplifier or oscillator. Because of its ratings, the tube is also well adapted to use in dielectric-heating equipment.

High operating efficiency is assured because of the small size and close spacing of the tube electrodes, the ring-seal construction, and the low-loss factor due to the gold-over-silver-plated external parts and the ceramic insulator. In addition, the grounded-grid construction eliminates the necessity for neutralization in a properly designed circuit. The small size of the GL-6183 permits compact mounting, and the ring-seal construction allows quick plug-in installation.

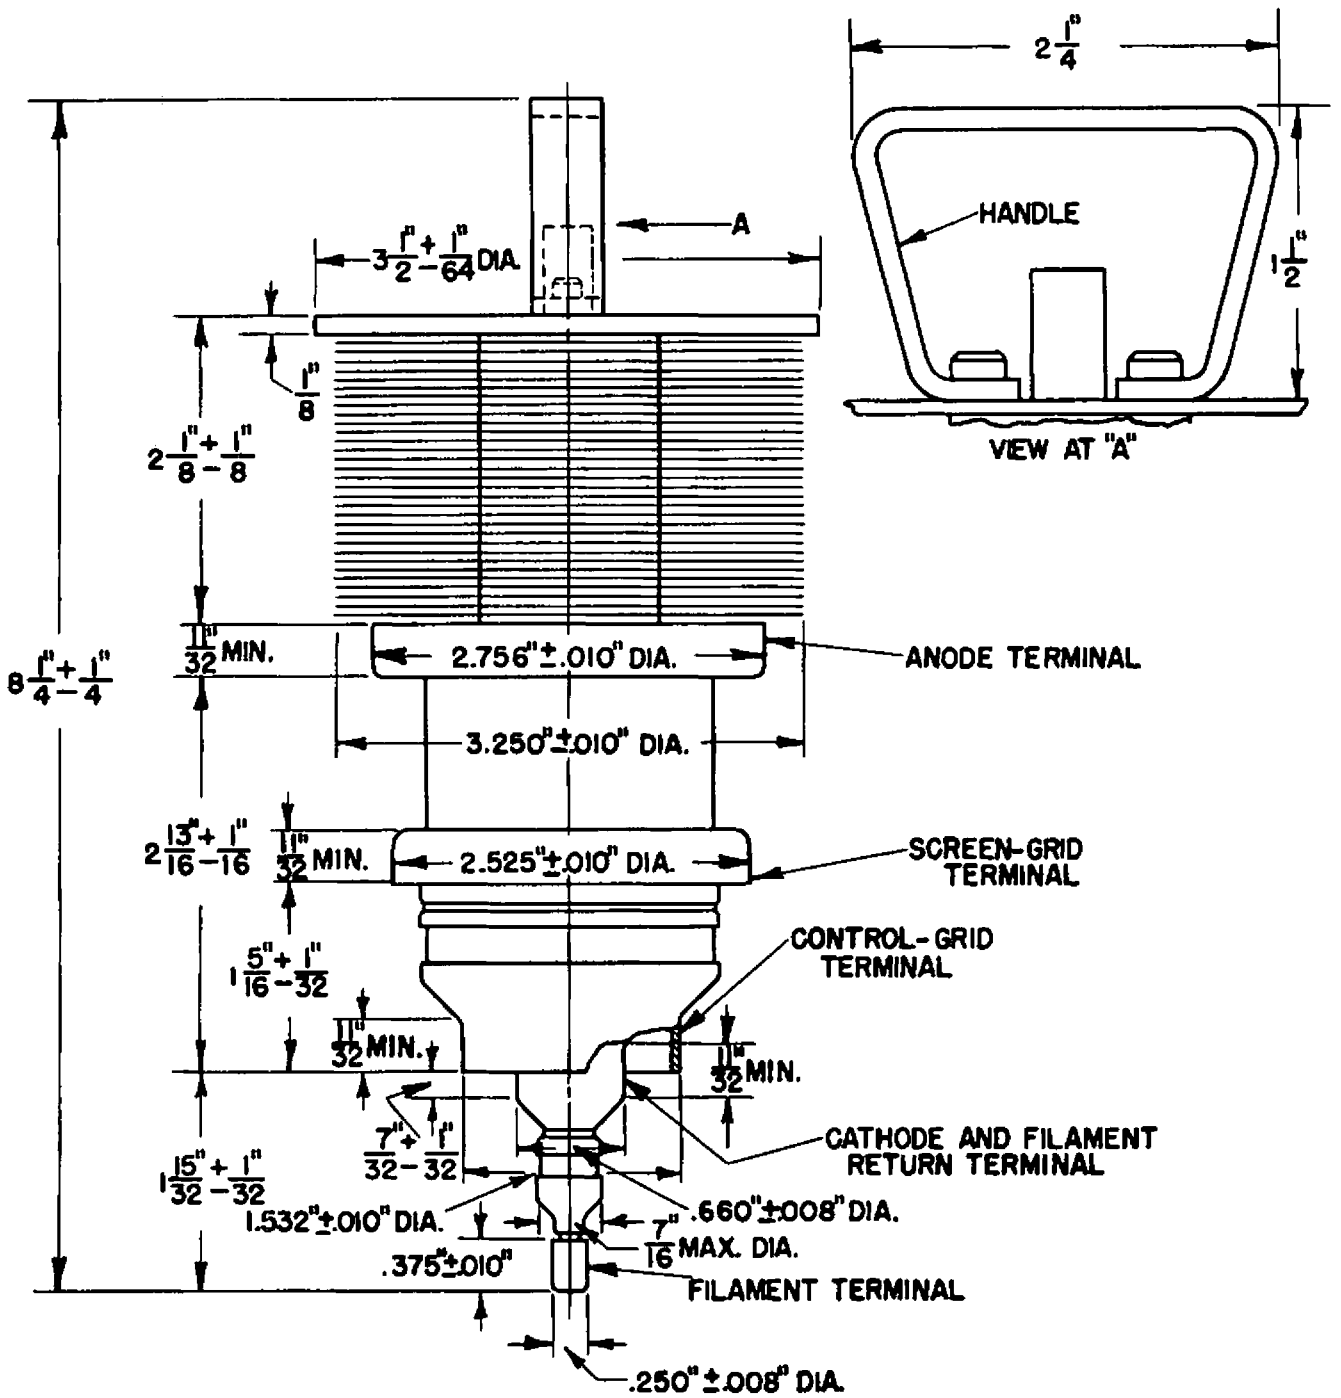
* The cathode of the GL-6183, because of transit-time effects which raise the temperature of the cathode is subjected to considerable back bombardment in ultra-high-frequency service. The amount of heating due to bombardment is a function of the operating conditions and frequency, and must be compensated for by a reduction of the heater input to prevent overheating of the cathode with resulting short life. For long life, the GL-6183 should be put in operation with rated heater voltage. After the circuit has been adjusted for proper tube operation, the heater voltage should be reduced to a value slightly above that at which circuit performance is affected. At a frequency of 900 megacycles and with typical operating conditions the heater voltage can be reduced to approximately 5 volts. At lower frequencies, the reduction will be less. Minor circuit readjustment may be necessary after this adjustment.

† Represents maximum useable cathode current (plate current plus current to each grid) for any condition of operation.

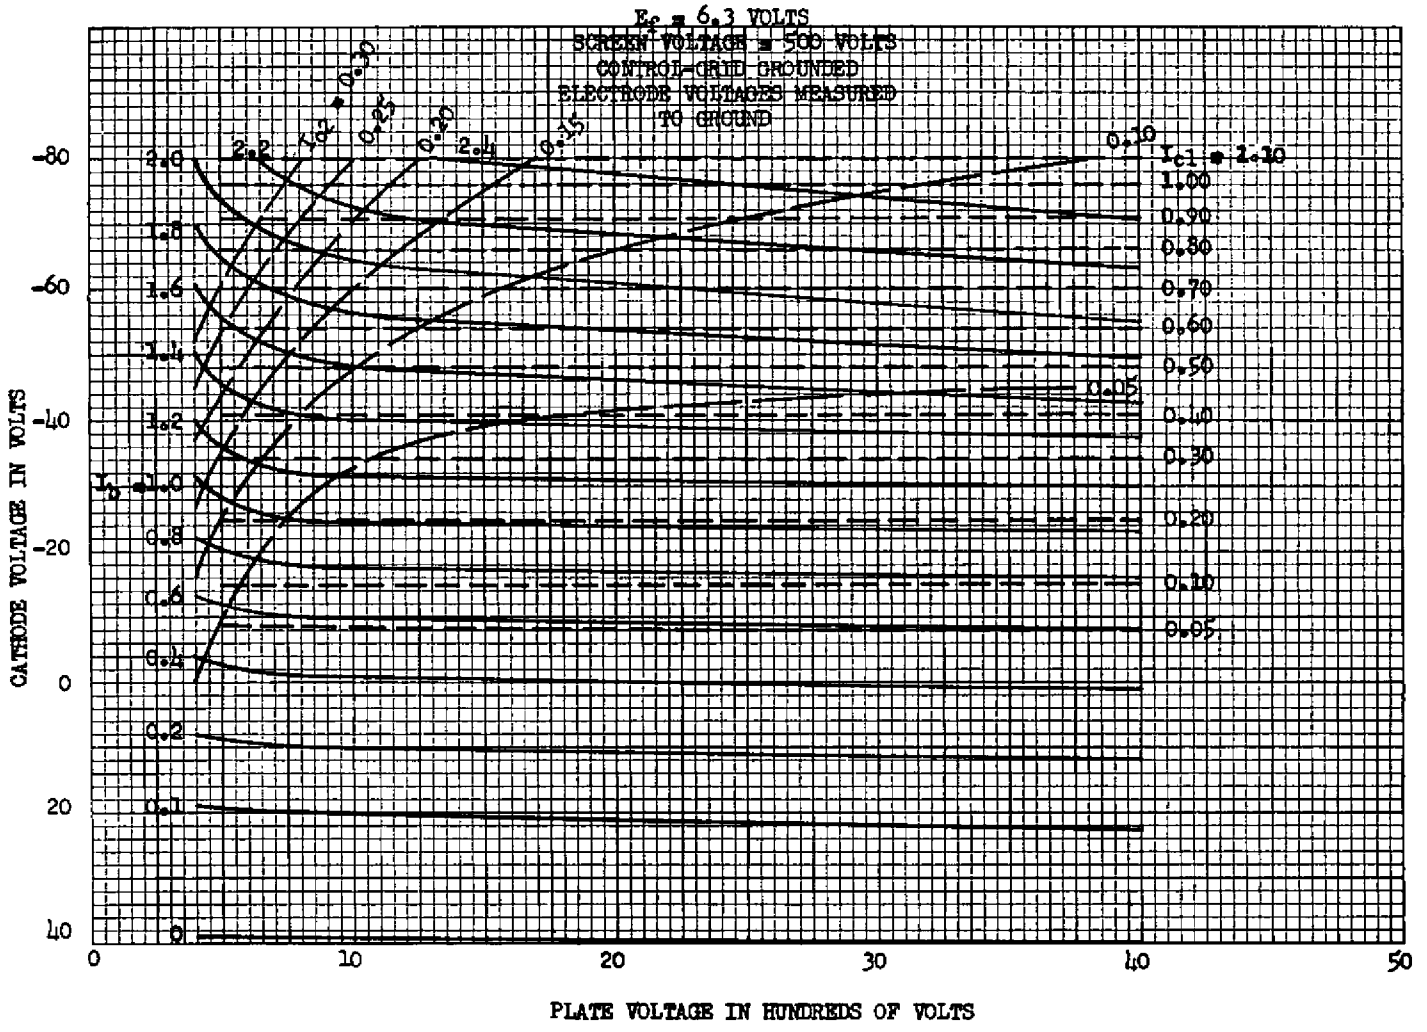


‡ Measured with a 6-inch diameter flat metal disk attached to the screen-grid ring. Control grid connected to the screen grid.

§ Output capacitance measured between anode and screen grid. Control grid connected directly to screen grid.

◊ Useful power output including power transferred from driver stage.

π Modulation essentially negative may be used if the positive peak of the envelope does not exceed 115 percent of the carrier conditions.



Δ Total anode power output including power transferred from driver stage.

TWIN TRIODE

DESCRIPTION

The GL-6201 is a miniature twin triode designed for use as a grounded-grid amplifier or as a frequency converter in very-high-frequency applications. The tube is specially designed to assure dependable life and reliable service under the exacting conditions encountered in mobile and aircraft applications. Features include a high degree of mechanical strength and a heater-cathode construction designed to withstand many-thousand cycles of intermittent operation.

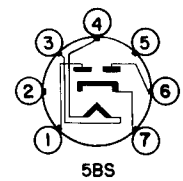
* To simplify the application of the maximum ratings to circuit design, the electrical design-center maximum ratings are also presented in chart form as Rating Charts I, II, and III. Rating Chart I presents the maximum ratings for a-c plate-supply voltage and d-c output current. Rating Chart II provides a convenient method for checking conformance with the maximum steady-state peak plate current rating. Rating Chart III offers a convenient method for checking conformance with the maximum transient peak plate current rating.

With a capacitor-input filter, the conditions of each of Rating Charts I, II, and III must be satisfied in order to obtain performance within all of the appropriate electrical maximum ratings. With a choke-input filter, operation within the indicated boundary of Rating Chart I will assure performance within all of the appropriate electrical maximum ratings.



† The altitude ratings as presented refer to the limitations of the tube itself. Because the socket employed can become the limiting factor in high-altitude operation, consideration must be given to the voltage-breakdown capabilities of the tube and socket combination employed.

‡ The maximum ratings for a-c plate supply voltage and d-c output current are interrelated and are also dependent on whether a choke or capacitor-input filter is employed. This relationship is shown in Rating Chart I. With a capacitor-input filter, the operating point of d-c output current and a-c supply voltage must fall within the curve FAEDG. With a choke-input filter, the operating point must fall within the curve FABCDG.

§ Forces in any direction as applied by the Navy-type, High Impact (flyweight) Shock Machine for Electronic Devices or its equivalent.

DESCRIPTION AND RATING

KLYSTRON

GL-6237 GL-6238 GL-6239 GL-6240 GL-6241 GL-6242

Tube Type	Frequency Range Megacycles	Television Channel Coverage
GL-6237	470 - 530	14 - 23
GL-6238	530 - 590	24 - 33
GL-6239	590 - 656	34 - 44
GL-6240	656 - 728	45 - 56
GL-6241	728 - 806	57 - 69
GL-6242	806 - 890	70 - 83

These tubes are three-resonator tunable klystrons for use as radio-frequency amplifiers. They cover the UHF television band, 470 to 890 megacycles, and each type will provide 12 kilowatts of power output at synchronizing peak level with a power gain of approximately 200 in broadband visual-amplifier service. Broadband operation is obtained by stagger-tuning the input and output resonators on the low side of the center frequency and the center resonator on the high side.

The tubes have unipotential tantalum disk-type cathodes heated by bombardment, collectors capable of dissipating 51 kilowatts, and require electro-magnetic focusing of the electron beam. The cathode seals and the output seals are forced-air cooled; the drift tubes and the collectors are water cooled. There will be two basic resonator diameters for the six types.

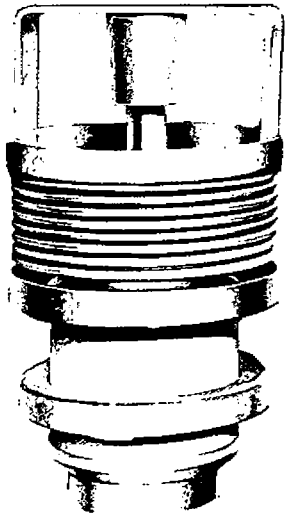
* The bogey value is the approximate value of bombarder heater voltage required to furnish just sufficient bombarder current which with a bombarder voltage of 2400 volts maintains the main cathode at an operating temperature adequate to furnish a beam current of 3 amperes. To avoid excessively long cathode-heating time the heater voltage should be started at approximately 8 volts and gradually reduced to the normal operating value as the cathode reaches the proper operating temperature. Voltage stability of the heater and bombarder supplies is important to prevent fluctuation in beam current.

† Approximate time required to permit normal operation. Beam voltage may be applied earlier.

‡ The magnetic field required will vary with the type and the channel to which the tube is tuned. It ranges between 300 and 400 gausses. Three independently regulated electromagnets around the body assembly and one around the cathode structure are required for proper electron-beam focusing. Details regarding the design and positioning of these magnets will be found in the Installation and Operation Instructions.

§

Approximate Weights



GL-6237	280	Pounds
GL-6238	280	Pounds
GL-6239	280	Pounds
GL-6240	180	Pounds
GL-6241	180	Pounds
GL-6242	180	Pounds

Δ The amount of beam current for a given beam voltage and power output will be approximately 2.5 amperes for the GL-6237 and will range up to 3 amperes for the GL-6242 since efficiency decreases somewhat at the higher frequencies.

π Saturation power level is the maximum radio-frequency power level which the tube will deliver for a given beam input power. Under operating conditions for a 15-kilowatt saturation level, the power output versus driving power characteristic is linear enough to permit application in video television up to a 12-kilowatt synchronizing peak level with a moderate amount of synchronizing peak pre-emphasis in the driver stage.

TUBE DEPARTMENT
GENERAL ELECTRIC

GL-6283
TETRODE

RADIO-FREQUENCY AMPLIFIER
CW SERVICE
GROUNDED-GRID OPERATION

The GL-6283 is a reliable power tetrode that delivers useful output to 1250 megacycles or higher. This tube is particularly suitable for application in the final output or driver stage of military-communications systems.

As a Class B linear amplifier in the 225–400-megacycle range, the tube will deliver 110 watts of carrier power modulated up to 100 percent. Since a power gain of 20 may be realized, drive requirements are low—approximately 5 watts at carrier level.

FORCED-AIR COOLED
METAL AND CERAMIC
INTEGRAL RADIATOR

Operating as a Class C CW amplifier at 900 megacycles, the gain is approximately 15 at the 200-watt level.

Features of the GL-6283 include long life and reliability, high gain, high linearity, and resistance to shock and vibration.

These together with such design factors as an oxide-coated cathode, coaxial elements, and metal-ceramic construction make the tube well adapted to application in modern systems where performance and reliability are important.

* Because the temperature of the cathode is increased by back bombardment of electrons at UHF, required heater voltage for optimum life decreases with increasing frequency. The amount of heater-voltage reduction is dependent on operating conditions. However, this voltage should not be less than 5.5 volts.
† Represents maximum usable cathode current (plate current plus current to each grid) for any condition of operation.
‡ Measured with a 6-inch minimum diameter flat metal disk attached to the screen-grid ring. Control grid connected to the screen grid.
♦ Output capacitances measured between anode and screen grid. Control grid connected directly to screen grid.
§ Forced-air cooling to be applied before and during the application of any voltages.
**Provision must be made for unobstructed passage of cooling air between radiator fins and between the anode terminal and adjacent radiator fin.
♥ Useful power output as measured in output-circuit load.
¶ Useful power output including power transferred from driver stage. Output circuit efficiency approximately 80 percent.
△ Modulation essentially negative may be used if the positive peak of the envelope does not exceed 115 percent of the carrier conditions.

MICROWAVE DEVICES

—PRODUCT INFORMATION—

Planar Triode

FOR GROUNDED-GRID CLASS A UHF AMPLIFIER APPLICATIONS

6299

The 6299 is a high-mu, metal-and-ceramic triode intended for operation as a grounded-grid, Class A radio-frequency amplifier at frequencies as high as 3000 megacycles.

Features of the tube include small size, planar electrode construction with close spacing, inherent rigidity, and an envelope structure convenient for coaxial circuit applications.

At 1200 megacycles a noise figure of less than 8.5 decibels may be obtained when the 6299 is used in a grounded-grid coaxial circuit.

In radar receivers, or similar applications, where the grid of the tube may be driven positive by leakage pulses, consideration should be given to use of the 7644 in place of the 6299.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron device of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The device manufacturer chooses these values to provide acceptable serviceability of the device, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the device under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any device under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the device under consideration and of all other electron devices in the equipment.

The devices and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of devices by General Electric Company conveys any license under patent claims covering combinations of these devices with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of these devices with other devices or elements by any purchaser or others.

NOTES

* The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

‡ Heater current of a bogey tube at Ef = 6.3 volts.

§ Without external shield.

¶ Good thermal contact to the anode and cathode must be provided to conduct heat from the elements. The anode contact must be sufficiently flexible to keep lateral force on the anode terminal at a minimum.

The 6299 is rated only for Class A amplifier service.

Δ Does not apply to initial-emission-velocity current.

¢ Adjusted for Ib = 10 milliamperes.

** Adjust for Ib = 10 milliamperes; range must be variable from 75 to 200 volts.

‡‡ Supply should be regulated.

§§ For operation above 1000 megacycles, the minimum noise figure will generally be obtained by operation at zero bias. For operation below 1000 megacycles, the use of a cathode resistor or grid bias should be evaluated for the particular application.

¶¶ Adjusted for Ib = 10 milliamperes; 200 ohm variable cathode resistor recommended.

IGNITRON

Temperature Controlled

The GL-6347 ignitron is a sealed, stainless-steel-jacketed, water-cooled, mercury-pool tube especially suited to resistance-welding-control service. In this service two tubes in the inverse-parallel connection will control 1200 kilovolt-amperes at voltages of 250 to 600 volts over the frequency range of 25 to 60 cycles. The ability of this tube to carry very high peak currents for short periods makes it especially suited to such service.

Ease of installation, economical use of space, and reliability of operation are assured by design and construction features inherent in the steel-jacketed construction.

This tube is identical in ratings and characteristics to the GL-5552/FG-235-A. Mechanically, it has the additional feature of an integral temperature-control device with protective features. The control includes a switch which operates a solenoid valve in the water-supply line to the tube in response to increasing and decreasing tube temperature, thus maintaining the amount of cooling water to the minimum required by the operating conditions. An over-temperature switch is included to remove power from the ignitron when its temperature exceeds a safe value. In applications where the cooling water flows through two tubes in series, this tube can be used with the GL-5552/FG-235-A since the GL-6347, in the position nearer the water drain where it receives the warmer water, can control the flow to both under normal conditions.

This new construction prevents excessive condensation over the external parts of the tube under conditions of high humidity. Another advantage is the appreciable saving in maintenance costs over tubes of the old design since this control feature, in addition to greatly reducing the amount of water required, eliminates the necessity for such safety devices as water-flow relays, water over-temperature relays, and water-pressure interlocks required with the older design tubes. The GL-6347 ignitron is equivalent to a 600-ampere magnetic contactor.

DESCRIPTION AND RATING

The 6386 is a miniature medium-mu twin triode in which each section exhibits a remote-cutoff characteristic. It is designed primarily for use as a cascode radio-frequency amplifier, intermediate-frequency amplifier, or mixer in circuits to which it is desired to apply automatic-gain-control. When used in cascode applications, the performance of the 6386 is characterized by high gain, low noise figure, and low higher-order harmonic distortion.

The 6386 is a special-quality tube intended for use in critical industrial and military applications in which operational dependability is of primary importance. Features of the tube include a high degree of mechanical strength and a heater-cathode construction capable of withstanding many-thousand cycles of intermittent operation. When used in on-off control applications, the tube will maintain its emission capabilities after long periods of operation under cutoff conditions.

6442
PLANAR TRIODE

DESCRIPTION AND RATING

FOR GROUNDED-GRID OSCILLATOR AND AMPLIFIER SERVICE

Metal and Ceramic — Small Size

Two Kilowatts Useful Pulse Power Output

The 6442 is a high-mu, metal-and-ceramic triode intended for operation as a plate-pulsed, grounded-grid oscillator at frequencies as high as 5000 megacycles. The 6442 is also useful as a CW, radio-frequency power amplifier or frequency multiplier at frequencies as high as 2500 megacycles.

Features of the 6442 include small size, planar electrode construction with close spacing, inherent rigidity, an envelope structure convenient for coaxial circuit applications, and excellent resistance to vibration and shock.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

* The equipment designer should design the equipment so that heater voltage is centered at some value within the range of 4.5 to 5.7 volts for CW operation, or 5.7 to 6.3 volts for pulse operation. Heater voltage variations about the center value should be kept as small as practical and should not, in any case, exceed ±5%. The optimum center value of heater voltage depends on the cathode current and on other parameters of circuit design and operation. For specific recommendations, contact your General Electric tube sales representative.

† Heater current of a bogey tube at Ef = 6.3 volts.

‡ Measured in a special shielded socket.

¶ Applications with a duty factor greater than 0.001 should be referred to your General Electric tube sales representative for recommendations.

⁂ In any 5000 microsecond interval.

△ The regulation and/or series plate-supply impedance must be such as to limit the peak current, with the tube considered a short circuit, to a maximum of 25 amperes.

** Modulation essentially negative may be used if the positive peak of the audio-frequency envelope does not exceed 115 percent of the carrier conditions.

PRELIMINARY DESCRIPTION AND RATING

IGNITRON GL-6504

The GL-6504 is a double-grid ignitron designed for railroad locomotive rectifier service. In this service twelve tubes will supply d-c power for a 4000-horsepower locomotive.

A coaxial cathode-current return provides magnetic shielding. The tube also features baffles in the mercury pool to assure contact between the mercury and the ignitor points during swaying of the equipment.

A companion tube, the GL-6509 ignitron, has been designed to supply the auxiliary power requirements of applications which use the 6504 as the main power source.

PRELIMINARY DESCRIPTION AND RATING

IGNITRON GL-6509

The GL-6509 is an ignitron for railroad locomotive rectifier service. This tube is designed to supply the auxiliary power requirements in those locomotives that utilize the GL-6504 ignitron as the main power supply. In addition to this service the 6509 ratings also make the tube particularly suitable for use as the main power source in multiple-unit car installations.

The tube is similiar in construction to the GL-5555/FG-238-B ignitron but has the additional feature of baffles in the mercury pool to assure contact between the mercury and the ignitor points during swaying of the equipment.

DESCRIPTION AND RATING

TEMPERATURE-CONTROLLED IGNITRON GL-6511

The GL-6511 ignitron is a sealed, stainless-steel jacketed, water-cooled mercury-pool tube for control of frequency-changer resistance welders. This method of resistance welding converts three-phase 60-cycle power to single-phase power at four to twelve cycles per second. A particular advantage of this method is the appreciable reduction of kilovolt-ampere demand from that required in single-phase welding, with consequent saving in the amount of power required. In addition, the three-phase circuit balances the power load and makes possible improved results in welding aluminum, magnesium, and their alloys.

This tube is identical in ratings and characteristics to the GL-5822. Mechanically, it has the additional feature of an integral temperature-control device with protective features. The control includes a switch which operates a solenoid valve in the water-supply line to the tube in response to increasing and decreasing tube temperature, thus maintaining the amount of cooling water to the minimum required by the operating conditions. It also includes an over-temperature switch which may be used to remove power from the ignitron when its temperature exceeds a safe value.

This new construction prevents excessive condensation over the external parts of the tube under conditions of high humidity. Another advantage is the appreciable saving in maintenance costs over tubes of the old design since this control feature, in addition to greatly reducing the amount of water required, eliminates the necessity for such safety devices as water-flow relays, water over-temperature relays, and water-pressure interlocks required with the older design tubes. In applications where the cooling water flows through three tubes in series, this tube can be used with the GL-5822 since the GL-6511, in the position nearer the water drain where it receives the warmer water, can control the flow to all under normal conditions.

DESCRIPTION AND RATING

TEMPERATURE-CONTROLLED IGNITRON GL-6512

The GL-6512 ignitron is a sealed, steel-jacketed, water-cooled, mercury-pool tube designed for rectifier service in the 125-, 250-, 600-, and 900-volt d-c power fields. It is suitable for use in rectifiers rated up to 200 kilowatts output, depending on the number of ignitrons used, the output voltage, and the circuit. It has a continuous average current rating of 100 amperes per tube for this service. The tube is also designed for 2400-volt a-c control service where it has a rating of 1200 kilovolt-amperes.

This tube is identical in ratings and characteristics to the GL-5554/FG-259-B. Mechanically, it has the additional feature of an integral temperature-control device with protective features. The control includes a switch which operates a solenoid valve in the water-supply line to the tube in response to increasing and decreasing tube temperature, thus maintaining the amount of cooling water to the minimum required by the operating conditions. It also includes an over-temperature switch which may be used to remove power from the ignitron when its temperature exceeds a safe value.

This new construction prevents excessive condensation over the external parts of the tube under conditions of high humidity. Another advantage is the appreciable saving in maintenance costs over tubes of the old design since this control feature, in addition to greatly reducing the amount of water required, eliminates the necessity for such safety devices as water-flow relays, water over-temperature relays, and water-pressure interlocks required with the older design tubes. In applications where the cooling water flows through two or three tubes in series, this tube can be used with the GL-5554/FG-259-B since the GL-6512 in the position nearer the water drain where it receives the warmer water, can control the flow to all under normal conditions.

Like its prototype, the GL-6512 has an auxiliary anode and two ignitors. Excitation of the auxiliary anode permits stabilizing the cathode spot for very small anode currents. The two ignitors assure long life since only one is used at a time. Phase control of the ignitor impulses permits voltage control of the rectified output. In common with other ignitors arc losses in the GL-6512 are low, and design and construction features inherent in the steel-jacketed construction assure ease of installation, economical use of space, and reliability of operation.

GL-6514

IGNITRON

DESCRIPTION AND RATING

The GL-6514 is a permanently sealed water-cooled rectifier ignitron similar in contruction and rating to the GL-5788. Special features are the addition of an integral temperature-control device with protective features, low water-pressure drop, and distinctive (larger diameter) ignitor terminals. The tube is designed for operation in 300, 600, and 900 volt d-c industrial rectifier circuits. The continuous average anode current rating is 200 amperes per tube in rectifiers rated up to 400 volts d-c. The control includes a switch which operates a solenoid valve in the water-supply line to the tube in response to increasing and decreasing tube temperature, thus maintaining the amount of cooling water to the minimum required by the operating conditions. It also includes an over-temperature switch which may be used to remove power from the ignitron when its temperature exceeds a safe value.

This new design of tube eliminates the need for the heat exchangers and recirculating water systems required to ensure safe operation of the non-temperature-controlled tube when the available cooling water temperature is too low to provide the minimum reliable mercury-vapor pressure in the tubes. Another advantage is that the temperature-controlled tubes can be used to replace the usual safety devices such as water-flow relays, water over-temperature relays, and water-pressure inter-locks which have required considerable maintenance in the past. Another advantage is that these tubes may be used to prevent excessive moisture condensation over the external parts of the tubes under conditions of high humidity.

DESCRIPTION AND RATING

TEMPERATURE-CONTROLLED IGNITRON GL-6515

The GL-6515 is a mercury-pool tube of permanently sealed steel construction designed for rectifier service in the 125-, 250-, 600-, and 900-volt d-c power fields. It is suitable for use in rectifiers rated up to 2000 kilowatts output, depending on the number of ignitrons used, the output voltage, and the circuit. Continuous average current rating is 400 amperes per tube in such service. The tube is also designed for 2400-volt a-c control service where it has a rating of 4800 kilovolt amperes.

This tube is identical in ratings and characteristics to the GL-5564/GL-507. Mechanically, it has the additional feature of an integral temperature-control device with protective features. The control includes a switch which operates a solenoid valve in the water-supply line to the tube in response to increasing and decreasing tube temperature, thus maintaining the amount of cooling water to the minimum required by the operating conditions. It also includes an over-temperature switch which may be used to remove power from the ignitron when its temperature exceeds a safe value.

This new construction prevents excessive condensation over the external parts of the tube under conditions of high humidity. Another advantage is the appreciable saving in maintenance costs over tubes of the old design since this control feature, in addition to greatly reducing the amount of water required, eliminates the necessity for such safety devices as water-flow relays, water over-temperature relays, and water-pressure interlocks required with the older design tubes. In applications where the cooling water flows through two or three tubes in series, this tube can be used with the GL-5564/GL-507 since the GL-6515, in the position nearer the water drain where it receives the warmer water, can control the flow to all under normal conditions.

Like its prototype, the GL-6515 has an auxiliary anode and two ignitors. Excitation of the auxiliary anode permits stabilizing the cathode spot for very small anode currents. The two ignitors assure long life since only one is used at a time. Phase control of the ignitor impulses permits voltage control of the rectified output. In common with other ignitrons arc losses in the GL-6515 are low, and design and construction features inherent in the steel-jacketed construction assure ease of installation, economical use of space, and reliability of operation.

Switch-Contact Arrangement		
Over-Temperature Switch - Normally Closed (Contacts Open on Temperature Rise)		
Water-Control Switch - Normally Open (Contacts Close on Temperature Rise)		

* At main anode voltages of 500 volts and over, the grid circuits should provide a negative d-c bias of 100 volts and a suitable turn-on voltage to swing the grid positive at the time the ignitor is fired. At lower anode voltages, it is sufficient to connect the grid to the main anode through a resistor. In either case, the grid-circuit resistance should be 500 to 1000 ohms.

† No more than three tubes should be connected in series for water flow. When the series connection is used the temperature of the incoming water must be within the rated limit for the warmest tubes in the series.

5 RMS demand voltage, current, and kilovolt-ampere demand are all on the basis of full-cycle conduction (no phase delay) regardless of where or not phase control is used. For voltages below the minimum, the minimum-voltage current rating applies. With the use of log-log paper straight-line interpolation between tabulated points may be used for other detailed ratings of: Demand kva vs average anode current, and maximum averaging time vs anode voltage.

11 Suitable fuses should be provided in the switch circuits to prevent a power arc should a ground occur in the switch or wiring.

Beam Pentode

6550-A

FOR AF POWER-AMPLIFIER APPLICATIONS

- AUDIO POWER OUTPUT
- UP TO 100 WATTS OUTPUT - 2 TUBES IN PUSH-PULL
- 42 WATTS PLATE DISSIPATION

The 6550-A is a beam-power pentode primarily designed for use in audio-frequency power-amplifier applications. It carries a 42 watt plate dissipation rating which provides for push-pull amplifier designs up to 100 watts output.

The 6550-A features a straight sided T-14 envelope and may be used as a direct replacement for the 6550.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

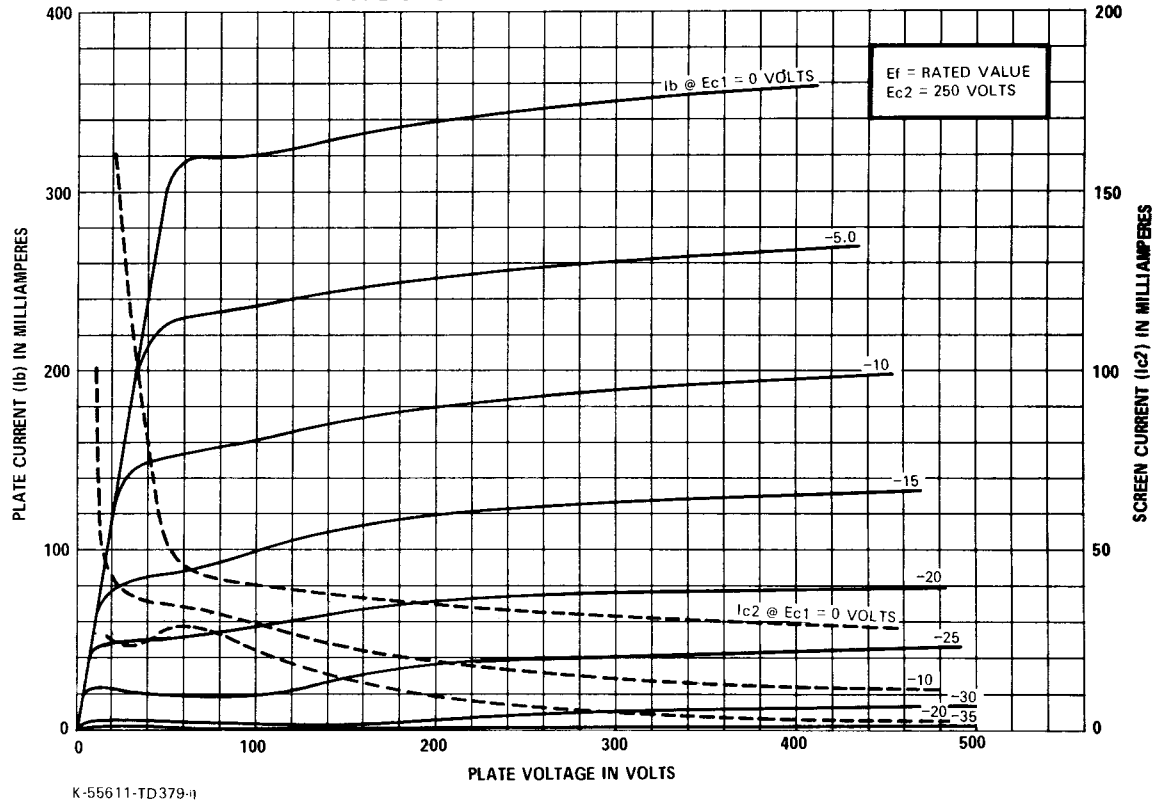
NOTES

* The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

● Heater current of a bogey tube at Ef = 6.3 volts.

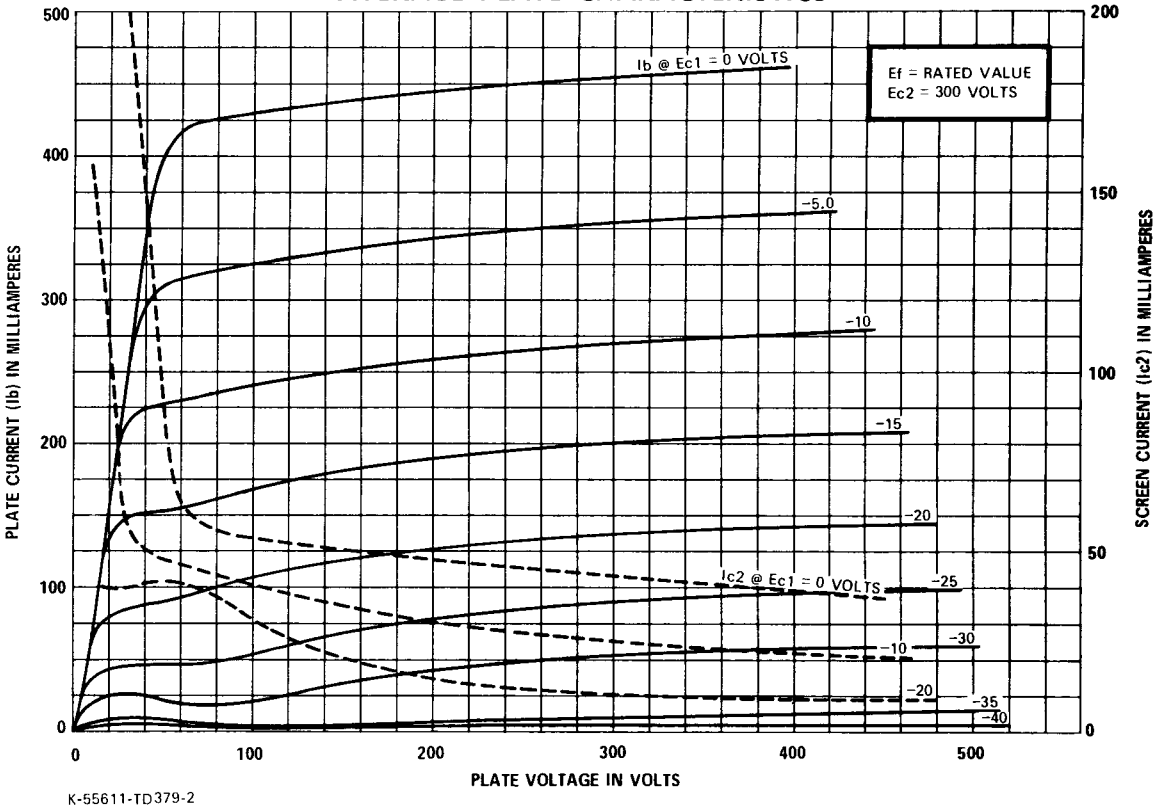
▲ Without external shield.



♦ With screen connected to plate.

§ The maximum screen voltage rating is 450 volts in push-pull circuits where the screen of each tube is connected to a tap on the plate winding of the output transformer.

⊕ Measured with an infrared thermometer, Ircon Model 700 BC or equivalent, at an ambient temperature of 40° C.



The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

GAS-DISCHARGE DEVICE

These gas-discharge devices are for use in polarization or branching-type duplexers in radar systems. In such service they perform the same function as A-TR and Pre-TR tubes and can be used to replace these switching tubes where higher power levels are required. In operation the gas-filled envelope ionizes to form a highly conductive gas column when high radio-frequency power is applied during the transmission period, and deionizes when the power is removed.

APPLICATION

GL-6619—Groups of ten to twenty in polarization twist duplexers, 2700 to 2900 megacycles.
GL-6620—Groups of two in branching-type duplexers, 3400 to 3600 megacycles.
GL-6621—Groups of ten to twenty in polarization twist duplexers, 2700 to 2900 megacycles.

GL-6625

KLYSTRON

960-1215 MEGACYCLES — INTEGRAL RESONATORS

22 KILOWATTS PEAK OUTPUT — ELECTROSTATICALLY FOCUSED

DESCRIPTION AND RATING

The GL-6625 is a three-resonator tunable amplifier klystron for pulsed operation up to a maximum duty of twelve percent. The tube covers a frequency range of 960 to 1215 megacycles and will provide a peak power output of 22 kilowatts. The unipotential cathode is oxide-coated and indirectly heated. The r-f output coupling is for 7/8-inch coaxial 50-ohm line and matches UG-1126/U connectors. The input and center-cavity-monitor fittings are BNC type to accommodate UG-88/U connectors. The tube is forced-air cooled, features mechanically tuned integral resonators, and is electrostatically focused, which eliminates the necessity for external magnets or focus coils.

6771
PLANAR TRIODE

DESCRIPTION AND RATING

FOR GROUNDED-GRID OSCILLATOR, AMPLIFIER, AND FREQUENCY MULTIPLIER SERVICE

Metal and Ceramic — Small Size

The 6771 is a high-mu, metal-and-ceramic triode intended for operation as a grounded-grid oscillator, radio-frequency power amplifier, or frequency multiplier at frequencies as high as 4000 megacycles. The 6771 is also useful as a plate-pulsed, grounded-grid oscillator at frequencies as high as 5000 megacycles.

Features of the 6771 include small size, planar electrode construction with close spacing, inherent rigidity, an envelope structure convenient for coaxial circuit applications, and excellent resistance to vibration and shock.

Grid Circuit Resistance	0.5	Megohms
Envelope Temperature at Hottest Point	175	C

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

* The equipment designer should design the equipment so that heater voltage is centered at some value within the range of 4.5 to 5.7 volts for CW operation, or 5.7 to 6.3 volts for pulse operation. Heater voltage variations about the center value should be kept as small as practical and should not, in any case, exceed ±5%. The optimum center value of heater voltage depends on the cathode current and on other parameters of circuit design and operation. For specific recommendations, contact your General Electric tube sales representative.

† Heater current of a bogey tube at Ef = 6.3 volts.

‡ Measured in a special shielded socket.

§ Modulation essentially negative may be used if the positive peak of the audio-frequency envelope does not exceed 115 percent of the carrier conditions.

¶ Applications with a duty factor greater than 0.001 should be referred to your General Electric tube sales representative for recommendations.

⁂ In any 5000 microsecond interval.

△ The regulation and/or series plate-supply impedance must be such as to limit the peak current, with the tube considered a short circuit, to a maximum of 12.5 amperes.

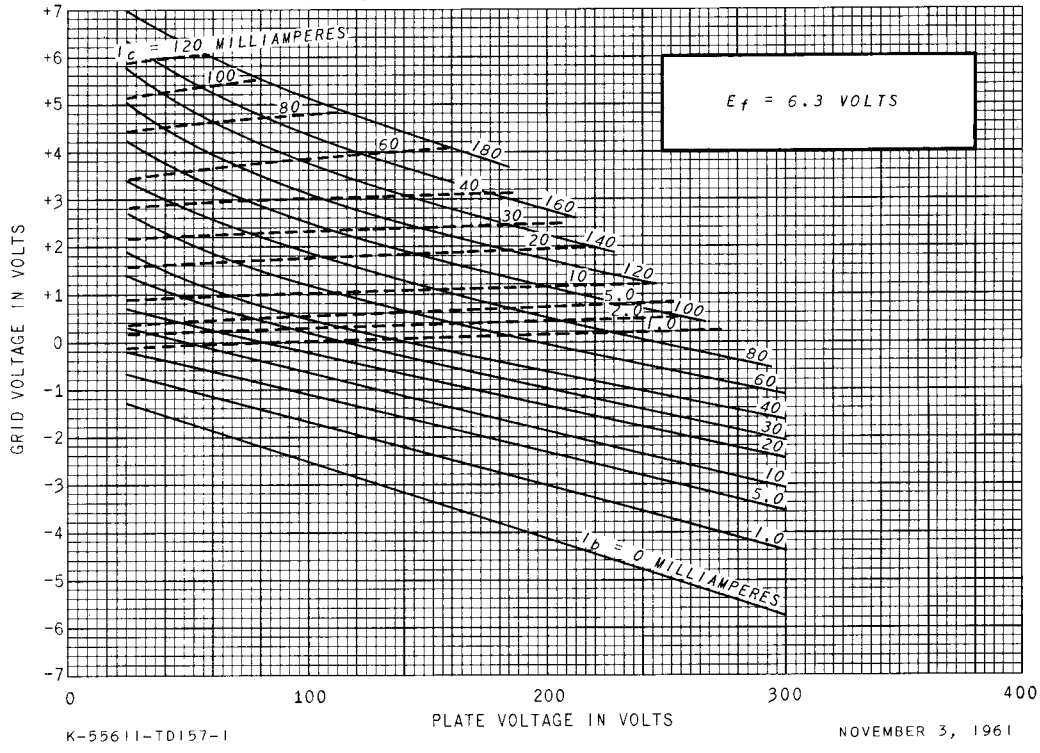
SPECIAL PERFORMANCE TESTS

	Min.	Max.	
Oscillator Power Output			
Tubes are tested for power output as an oscillator under the following conditions: Ef = 4.5 volts; F = 4000 MC, min.; Eb = 275 volts, Ec adjusted for Ib = 25 ma	200	...	Milliwatts
Low Pressure Voltage Breakdown Test			
Statistical sample tested for voltage breakdown at a pressure of 20 mm Hg. Tubes shall not give visual evidence of flashover when 500 volts RMS, 60 cps, is applied between the plate and grid terminals.			

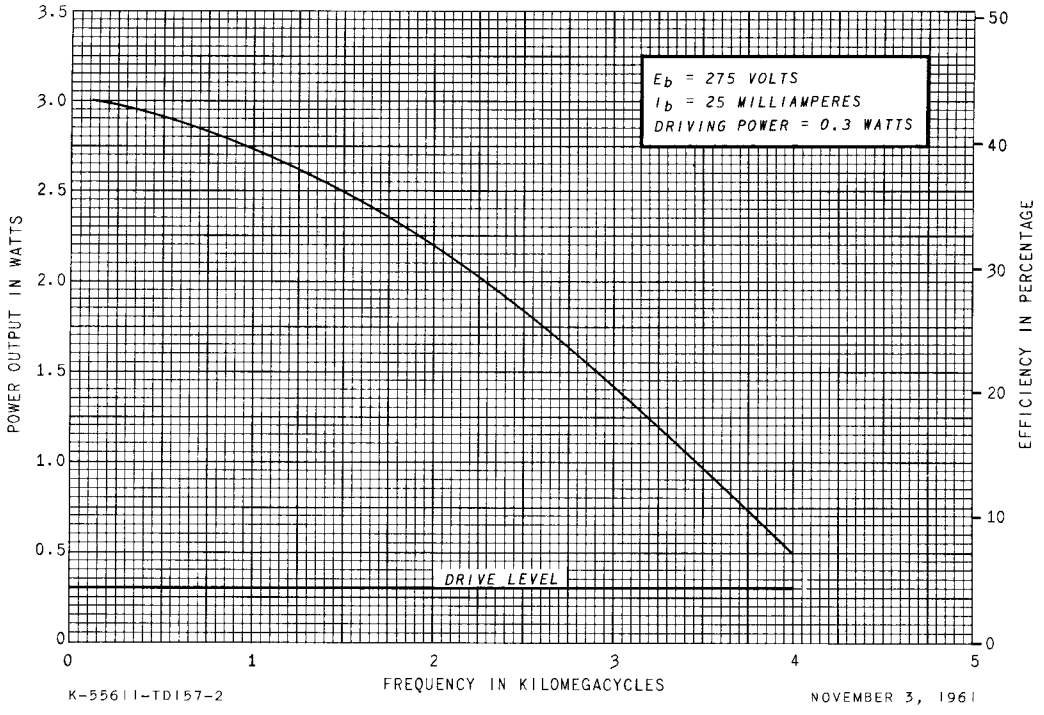
DEGRADATION RATE TESTS

Shock



Statistical sample subjected to 5 impact accelerations of approximately 400 G and 1.0 milliseconds duration in each of four positions. The accelerating forces are applied by the Navy-type, High Impact (flyweight) Shock Machine.

1000-Hour Life Test



Statistical sample operated for 1000 hours as an oscillator to evaluate changes in power output with life.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

Note 1. Applies to minimum surface for anode d-c and r-f terminal only. Other surfaces must not be used for these terminal purposes.

Note 2. Applies to minimum surface for grid d-c and r-f terminal only. Other surfaces, except for Notes 3 and 4, must not be used for terminal purposes.

Note 3. Applies to minimum surfaces for grid d-c and r-f terminal only.

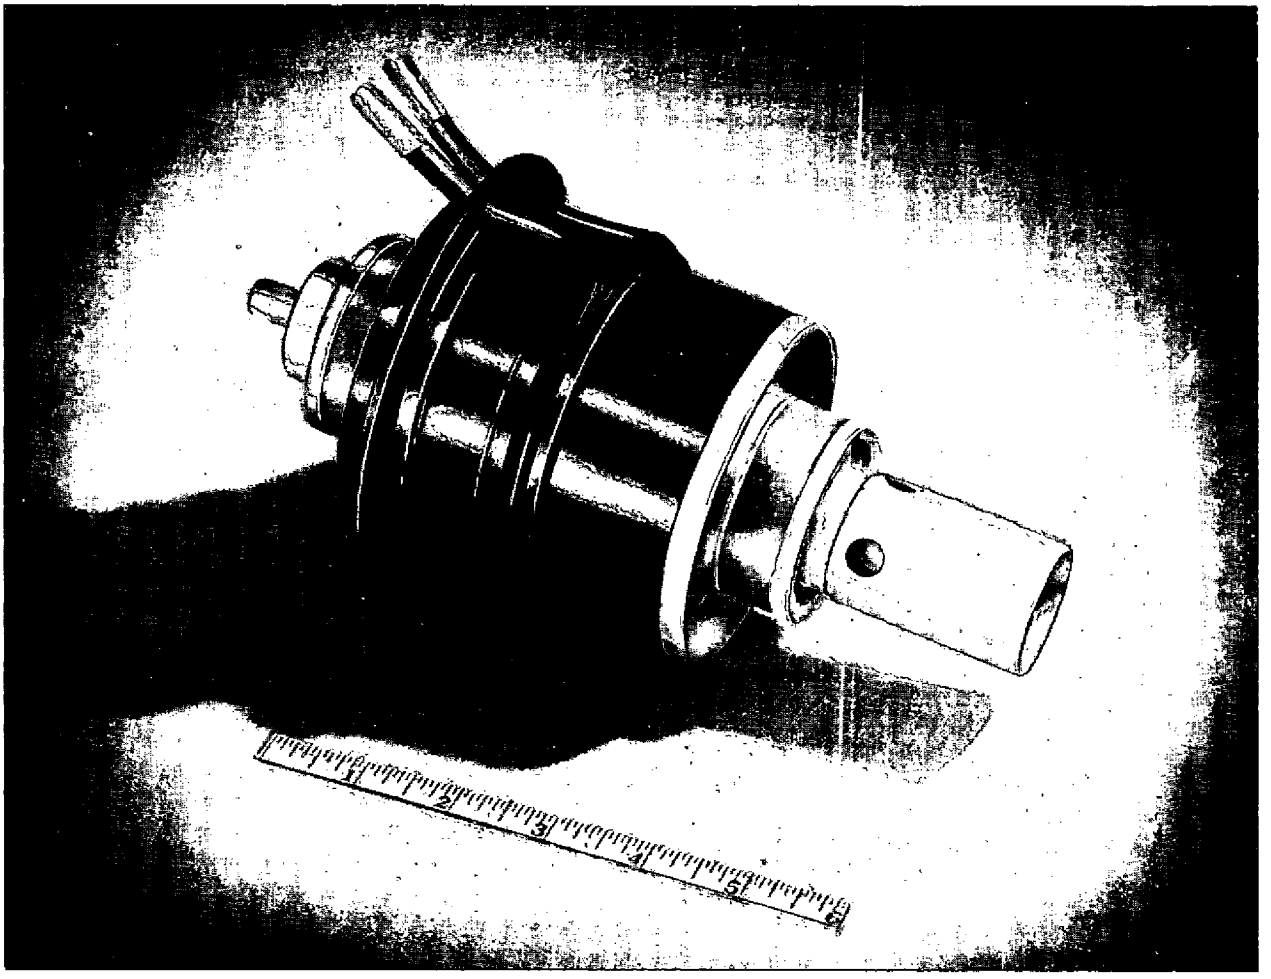
Note 4. The cylindrical surface of this diameter may be used for grid d-c and r-f terminal purposes.

Note 5. The surfaces defined by Notes 2, 3, and 4 shall be the only surfaces used for tube stops and clamping purposes.

Note 6. Other surfaces shall not be used for cathode d-c and r-f terminal purposes.

Note 7. Other surfaces shall not be used for anode d-c and r-f terminal purposes.

Note 8. Applies to surface designated for cathode d-c and r-f terminal. Solder at brazed joint will not exceed the maximum diameter.



Note 9. The maximum eccentricity of the anode and cathode with respect to the grid terminal in a prescribed jig is 0.010 (or maximum total runout of 0.020) and is measured by indicators at the points designated.

Note 10. The maximum eccentricity of heater-terminal No. 1 and heater-terminal No. 2 with respect to the grid terminal in a prescribed jig is 0.015 (or maximum total runout of 0.030) and is measured by indicators at the points designated.

Note 11. Exhaust tubulation must not be subjected to any mechanical stress.

Note 12. For reference only. Dimension does not include any possible solder fillet.

Note 13. This area is reserved for tube stamping and coding.

CW MAGNETRON

METAL AND CERAMIC

2.5 KILOWATTS OF CW POWER

FOR DIELECTRIC HEATING

915 MEGACYCLES

TUNGSTEN FILAMENT

HIGH EFFICIENCY

The GL-6787 is a water and forced-air-cooled CW magnetron designed for use as a power source in dielectric heating. It can produce 2.5 kilowatts of useful power and operates at a fixed frequency between 890 and 940 megacycles. The magnetic field is supplied externally, and may be an electromagnet connected in series with the plate current.

Magnetic Field—See K-69087-71A286 on page five for details.

* While the magnetron is oscillating, a portion of the input plate power (depending on load conditions) will cause the filament to overheat. Maximum life will be obtained by reducing the filament power during oscillation; if the loading changes rapidly, this reduction can best be done by an automatic control, otherwise, a manual correction may be used. The required reduction of power can be ascertained by decreasing the filament voltage until the hot filament resistance during oscillation is the same as that when the magnetron is not oscillating.

GL-6808

THYRATRON

TRIODE TYPE — QUICK-HEATING CATHODE

DESCRIPTION AND RATING

The GL-6808 is a three-electrode, inert-gas-filled thyratron with a negative control characteristic for all control applications. This tube combines the desirable temperature characteristic of gas tubes, maximum ratings over a wide temperature range, with the long life of mercury tubes. Another feature useful in industrial applications is the quick-heating cathode which requires only one minute to reach operating temperature.

The GL-6808 is equipped with a bracket-type base for panel mounting.

Maximum Positive Control-Grid Current		
Anode Positive	0.20	Amperes
Anode Negative	0.10	Amperes
Commutation Factor ⁄	130	
Ambient Temperature Limits	-55 to +70	C

Most satisfactory performance and life will result with quadrature filament operation, i.e., with the filament voltage 90 degrees out of phase with the anode voltage. When quadrature operation is used the voltage on the filament lead (lead No. 2) adjacent to the grid lead (lead No. 1) should be crossing zero from positive toward negative when the anode voltage is at the peak of the positive half cycle.

In three-phase systems each tube should be connected so that its anode and filament voltages approximate as nearly as possible the quadrature phasing, i.e., filament voltage 90 plus or minus 30 degrees out of phase with the anode voltage.

When quadrature operation is not practicable, filament lead No. 2 should be negative when the anode is positive.

⁄ Commutation factor is the product of the rate of current decay in amperes-per microsecond just prior to commutation, and the rate of inverse voltage rise in volts-per-microsecond just after commutation.

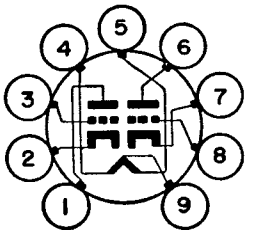
HIGH PERVEANCE
MEDIUM-MU



SHOCK, VIBRATION RATINGS
HEATER-CYCLING RATING

DESCRIPTION AND RATING

The 6840 is a miniature medium-mu twin triode primarily designed for service in computer applications. As required for this service, the tube incorporates an extremely high zero-bias plate current and a sharp-cutoff characteristic.

Intended for use in critical industrial and military applications in which operational dependability is of primary importance, the 6840 exhibits a high degree of mechanical strength and incorporates a heater-cathode construction capable of withstanding many-thousand cycles of intermittent operation. When used in on-off control applications, the tube will maintain its emission capabilities after long periods of operation under cutoff conditions.

† Design-Maximum Ratings are the limiting values expressed with respect to bogie tubes at which satisfactory tube life can be expected to occur for the types of service for which the tube is rated. Therefore, the equipment designer must establish the circuit design so that initially and throughout equipment life no design-maximum value is exceeded with a bogie tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, and environmental conditions.

††Rating based on a pulse of 10 microsecond duration, 1 percent duty cycle, and 1000-cycle repetition rate.

§ For pulse voltages of less than 1-percent duty cycle, the peak voltage may be 150 volts maximum.

	1000-Hr§§	350	....	Milliamperes

ϕ Regular Intermittent Life Test: Conditions of operation for each section are Ef = 12.6 volts, Eb = 250 volts, Rk = 620 ohms, Rg = 0.5 meg, Ehk = 180 volts with heater positive with respect to cathode, and bulb temperature = 185 C minimum.

**Zero-Bias Life Test: Conditions of operation for each section are Ef = 12.6 volts, Ebb = 125 volts, R_L = 1500 ohms, and Ic = 200 μa (Rg = 0.62 meg to +125 volts).

‡ Cutoff Life Test: Conditions of operation for each section are Ef = 12.6 volts, Eb = 150 volts, Ec = −30 volts, Rg = 0.1 meg, and Ehk = 180 volts with heater positive with respect to cathode.

§§Pulse Life Test: Conditions of operation for each section are Ef = 12.6 volts, Ebb = 180 volts, Ecc = −30 volts, R_L = 50 ohms, and Rg = 25 ohms. Grid is driven with a 25 volt positive-going pulse (measured on driver side of Rg) of 1 percent duty cycle and 1000-cycle repetition rate.

SPECIAL TESTS AND RATINGS

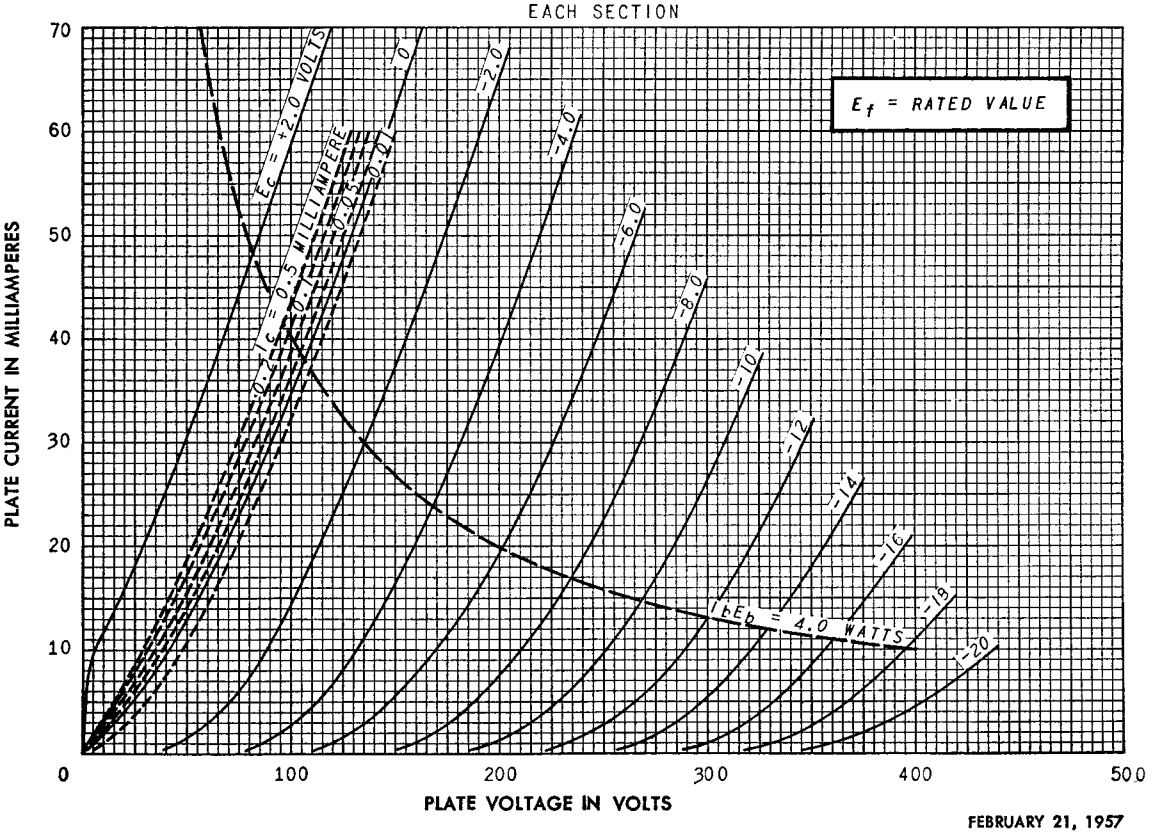
Stability Life Test
Statistical sample operated for one hour to evaluate and control initial variations in zero-bias plate current.

Survival-Rate Life Test
Statistical sample operated for one hundred hours to evaluate and control early life electrical and mechanical inoperatives.

Heater-Cycling Life Test
Statistical sample operated for 2000 cycles minimum to evaluate and control heater-cathode defects. Conditions of test include Ef = 7.5 volts (parallel-heater connection) cycled for one minute on and one minute off, Eb = Ec = 0 volts, and Ehk = 135 volts with heater positive with respect to cathode.

Shock Rating—450 G
Statistical sample subjected to five impact accelerations of 450 G in each of four different positions. The accelerating forces are applied by the Navy-type, High Impact (flyweight) Shock Machine for Electronic Devices or its equivalent.

Fatigue Rating—2.5 G
Statistical sample subjected to vibrational acceleration of 2.5 G for 32 hours minimum in each of three different positions. The sinusoidal vibration is applied at a fixed frequency between 25 and 60 cycles per second.



Cathode-Interface Impedance Life Test
Statistical sample operated without cathode current to evaluate and control the development of cathode interface impedance.

Altitude Rating—60,000 Feet
Statistical sample subjected to pressure of 55 millimeters of mercury to evaluate and control arcing and corona.

Note: The conditions for some of the indicated tests have deliberately been selected to aggravate tube failures for test and evaluation purposes. In no sense should these conditions be interpreted as suitable circuit operating conditions.

GL-6848
TETRODE

VHF-UHF **FORCED-AIR COOLED**

RING-SEAL CONSTRUCTION **METAL AND CERAMIC**

GROUNDED-GRID CIRCUIT

The GL-6848 is a four-electrode transmitting tube featuring a metal-and-ceramic envelope for use as a power amplifier or oscillator in grounded-grid circuits with both grids maintained at radio-frequency ground potential. The output circuit is connected between the anode and the screen grid. The anode is capable of dissipating 2 kilowatts. Cooling is accomplished by forced air with the radiator an integral part of the anode. The cathode is a unipotential thoriated-tungsten cylinder, heated by electron bombardment. Maximum ratings apply up to 800 megacycles, although higher frequency operation is possible.

In narrow band, Class C, grounded-grid, amplitude-modulated service, the GL-6848 has a useful carrier-power output in excess of one kilowatt. In Class C Telegraphy, it has a useful power output of 3.0 kilowatts of continuous power as an amplifier or oscillator.

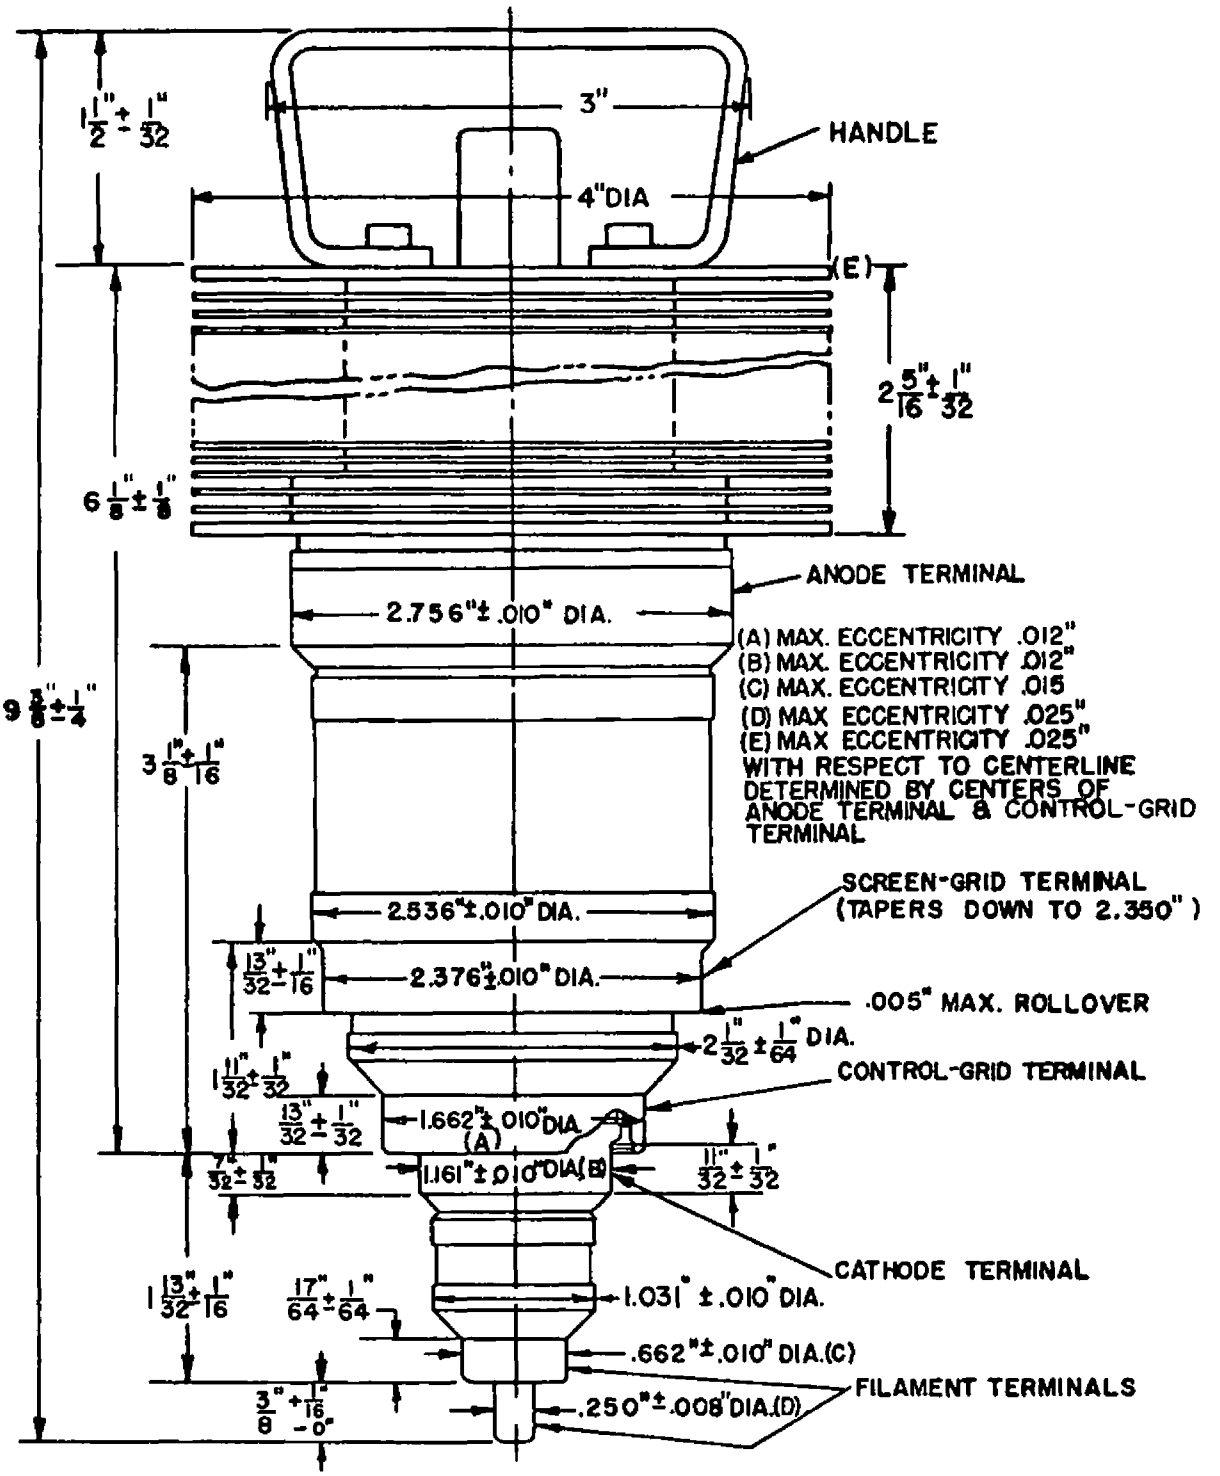
Cathode Bombarding Current, approximate	0.250	Ampere

* The cathode of the GL-6848, because of transit-time effects which raise the temperature of the cathode, is subjected to considerable back bombardment in ultra-high-frequency service. The amount of heating due to bombardment is a function of the operating conditions and frequency, and must be compensated for by a reduction of the cathode power input to prevent overheating of the cathode with resulting short life. In any case it is important from a tube life standpoint to keep the cathode power at as low a level as possible consistent with required performance. Bombarder power should be monitored by a suitable wattmeter or DC voltmeter and milliammeter arrangement. For long life, the tube should be put in operation with about 180 watts bombarding power. After the circuit has been adjusted for proper tube operation, bombarding voltage should be reduced to a value slightly above that at which circuit performance is affected. Minor circuit readjustment may be necessary after the above adjustment. The procedure for determining proper bombarding power should be repeated periodically.



† A bombarder supply designed for an output of 700 volts with a load of 300 milliamperes will serve adequately.

‡ Represents maximum usable cathode current.(plate current plus current to each grid) for any condition of operation.

§ Measured with complete isolation between cathode and plate.

¶ Output capacitance measured between anode and screen grid. Control grid connected directly to screen grid.

\# Useful power output including power transferred from driver stage.

GL-6855

THYRATRON

TRIODE TYPE — QUICK-HEATING CATHODE

NEGATIVE CONTROL CHARACTERISTICS — INERT-GAS AND MERCURY-VAPOR TYPE

DESCRIPTION AND RATING

The GL-6855 is a three-electrode inert-gas and mercury-vapor thyratron with negative control characteristics for use in all control applications. The GL-6855 combines the desirable temperature characteristic of gas tubes, maximum ratings over a wide temperature range, with the long life of mercury tubes. Another feature useful in industrial applications is a quick-heating filamentary-type cathode - only 15 seconds is required for the cathode to reach operating temperature.

GL-6878

IGNITRON

LOCOMOTIVE RECTIFIER SERVICE - 675 AMPERES — THREE IGNITORS

DESCRIPTION AND RATING

The GL-6878 is a double-grid ignitron designed for railroad locomotive rectifier service.

A coaxial cathode-current return reduces magnetic fields due to tube currents. The tube also features baffles in the mercury pool to assure contact between the mercury and the ignitor points during swaying of the equipment.

A companion tube, the GL-6509 ignitron, has been designed to supply the auxiliary power requirements of applications which use the GL-6878 as the main power source.

PLANAR TRIODE

DESCRIPTION AND RATING

FOR GROUNDED-GRID OSCILLATOR AND AMPLIFIER SERVICE

Metal and Ceramic — Low Interelectrode Capacitances
High Transconductance — Shock Resistant
100 Watts Plate Dissipation

The 6897 is a metal-and-ceramic, high-mu triode designed for use as a grounded-grid oscillator or amplifier at frequencies as high as 2500 megacycles.

Features of the 6897 include planar electrode construction, high plate dissipation capability, excellent electrode isolation, low radio-frequency losses, high transconductance, and low interelectrode capacitances.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

CHARACTERISTICS AND TYPICAL OPERATION

DC Grid Voltage	−40	−22	Volts
Useful Power Output	40	17	Watts

* The equipment designer should design the equipment so that heater voltage is centered at some value within the range of 4.5 to 6.3 volts. Heater voltage variations about the center value should be kept as small as practical and should not, in any case, exceed ±5%. The optimum center value of heater voltage depends on the cathode current and on other parameters of circuit design and operation. For specific recommendations, contact your General Electric tube sales representative.

† Heater current of a bogey tube at Ef = 6.3 volts.

‡ Measured in a special shielded socket.

§ Modulation essentially negative may be used if the positive peak of the audio-frequency envelope does not exceed 115 percent of the carrier conditions.

⁂ Where long life and reliable operation are important, lower envelope temperatures should be used.

¶ For modulation factors less than 1.0, a higher d-c plate voltage may be used if the sum of the peak positive audio voltage and the d-c plate voltage does not exceed 1200 volts.

△ Adjusted for Ib = 75 milliamperes.

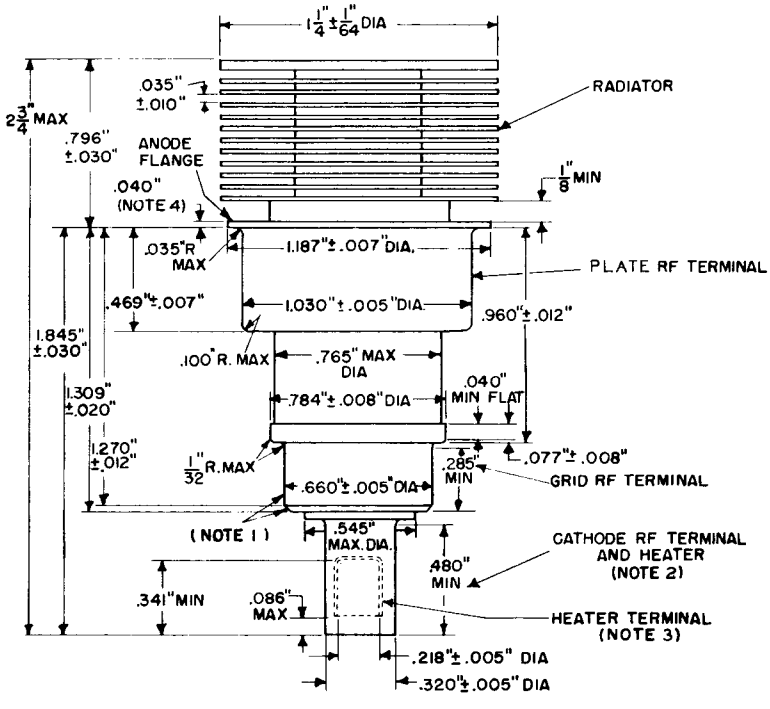
SPECIAL PERFORMANCE TESTS

	Min.	Max.	
Oscillator Power Output Tubes are tested for power output as an oscillator under the following conditions: Ef = 5.0 volts; F = 2500 MC, min.; Eb = 1000 volts; Ib = 90 ma.	15	....	Watts
Low Pressure Voltage Breakdown Test Statistical sample tested for voltage breakdown at a pressure of 27 mm Hg. Tubes shall not give visual evidence of flashover when 1000 volts RMS, 60 cps, is applied between the plate and grid terminals			

DEGRADATION RATE TESTS



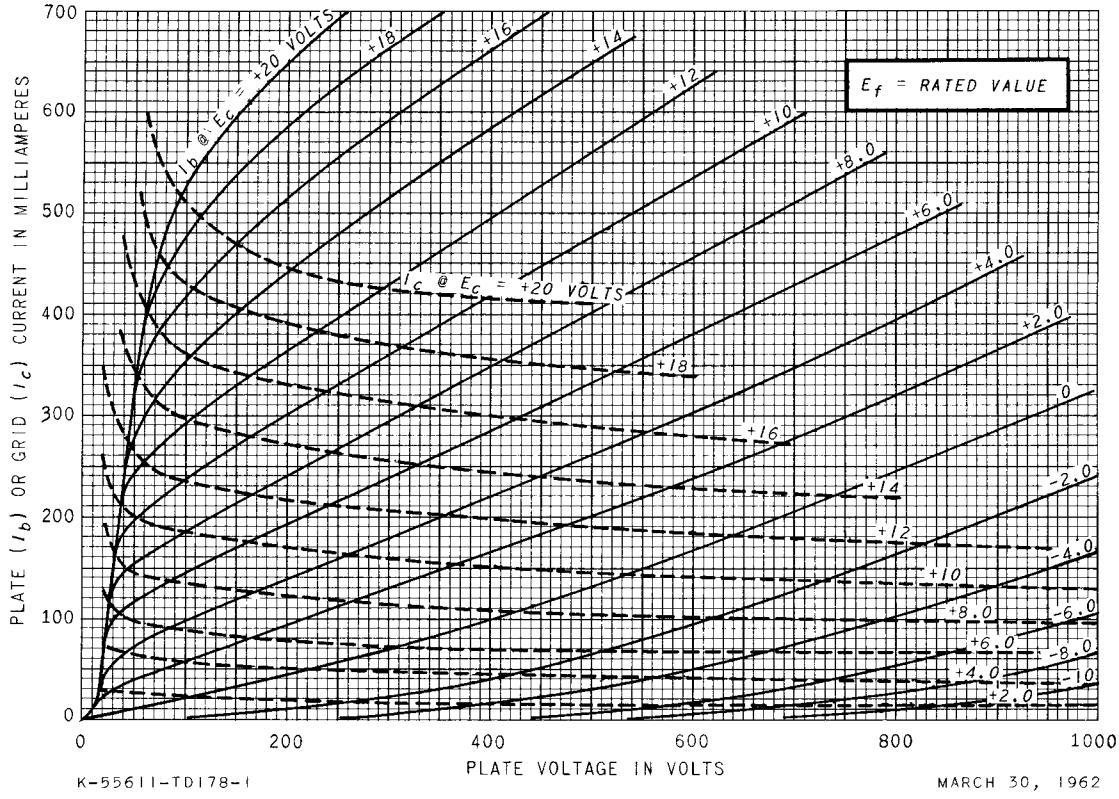
Shock

Statistical sample subjected to 5 impact accelerations of approximately 400 G and 1.0 milliseconds duration in each of four positions. The accelerating forces are applied by the Navy-type, High Impact (flyweight) Shock Machine.

500-Hour Life Test

Statistical sample operated for 500 hours as an oscillator to evaluate changes in power output with life.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.



NOTES:

1. Solder not to extend radially beyond grid RF terminal.
2. Total indicated runout of the grid-contact surface and the cathode-contact surface with respect to the anode shall not exceed 0.020".
3. Total indicated runout of the cathode-contact surface with respect to the heater-contact surface shall not exceed 0.012".
4. Only this flange to be used as a socket stop and clamp.

VOLTAGE-TUNABLE MAGNETRON

METAL AND CERAMIC
POWER OUTPUT—10 WATTS
2000-4000 MEGACYCLES
VOLTAGE-TUNED OVER FREQUENCY RANGE

The GL-6917 is a CW interdigital voltage-tunable magnetron for operation in the 2000-to-4000-megacycle range. In a narrow-band circuit, this tube has a power output up to 10 watts. In a circuit covering 2000 to 4000 megacycles, it has a power output up to 1.0 watt.

A novel ceramic-to-metal seal construction results in a tube extremely small in size—⅝ inch long and ¾ inch in diameter—and one which is particularly suitable for operation at microwave frequencies.

The GL-6917, in an external r-f circuit, may be voltage-tuned over a portion or all of the frequency range for which it is designed. The frequency of the generated signal is a linear function of the anode voltage. The r-f power output at any frequency is a function of the impedance of the external r-f circuit.

* Most satisfactory performance and life will result with quadrature filament operation, i.e., with the filament voltage 90 degrees out of phase with the anode voltage. When quadrature operation is used the voltage on the filament and cathode terminal should be crossing zero from positive toward negative when the anode voltage is at the peak of the positive half cycle.

In three-phase systems each tube should be connected so that its anode and filament voltages approximate as nearly as possible the quadrature phasing, i.e., filament voltage 90 plus or minus 30 degrees out of phase with the anode voltage.

When quadrature operation is not practicable, the filament and cathode terminal should be negative when the anode is positive.

The anode and grid-circuit returns should be made to the filament and cathode terminal. However, they can be made to the center tap of the filament transformer.

TETRODE

ONE KILOWATT UHF TELEVISION OUTPUT — FORCED-AIR COOLED

UHF TETRODE — METAL AND CERAMIC

GROUNDED-GRID CIRCUITS — INTEGRAL RADIATOR

THORIATED TUNGSTEN CATHODE

DESCRIPTION AND RATING

The GL-6942 is a four-electrode transmitting tube featuring a metal-and-ceramic envelope designed for use as a power amplifier or oscillator in grounded-grid circuits with both grids maintained at radio-frequency ground potential. The output circuit is connected between the anode and the screen grid. The anode is capable of dissipating one and one-half kilowatts. Cooling is accomplished by forced air with the radiator an integral part of the anode. The cathode is indirectly heated thoriated tungsten. Maximum ratings apply up to 900 megacycles.

When used as a Class B grounded-grid broad-band television amplifier this tube has a useful synchronizing peak-power output of one kilowatt at 900 megacycles; in narrow band Class C service the output is one kilowatt of continuous power as an amplifier or oscillator. Because of its ratings, the tube is also well adapted to use in dielectric-heating equipment.

High operating efficiency is assured because of the small size and close spacing of the tube electrodes, the ring-seal construction, and the low-loss factor due to the silver-plated external parts and the ceramic insulators. In addition, the grounded-grid construction eliminates the necessity for neutralization in a properly designed circuit. The small size of the GL-6942 permits compact mounting, and the ring-seal construction allows quick plug-in installation.

* The cathode of the GL-6942 because of transit-time effects which raise the temperature of the cathode, is subjected to considerable back bombardment in ultra-high-frequency service. The amount of heating due to bombardment is a function of the operating conditions and frequency, and must be compensated for by a reduction of the heater input to prevent overheating of the cathode with resulting short life. For long life, the GL-6942 should be put in operation with rated heater voltage. After the circuit has been adjusted for proper tube operation the heater voltage should be reduced to a value slightly above that at which circuit performance is affected. At a frequency of 900 megacycles and with typical operating conditions the heater voltage can be reduced to approximately 5.3 volts. At lower frequencies, the reduction will be less. Minor circuit readjustment may be necessary after this adjustment.

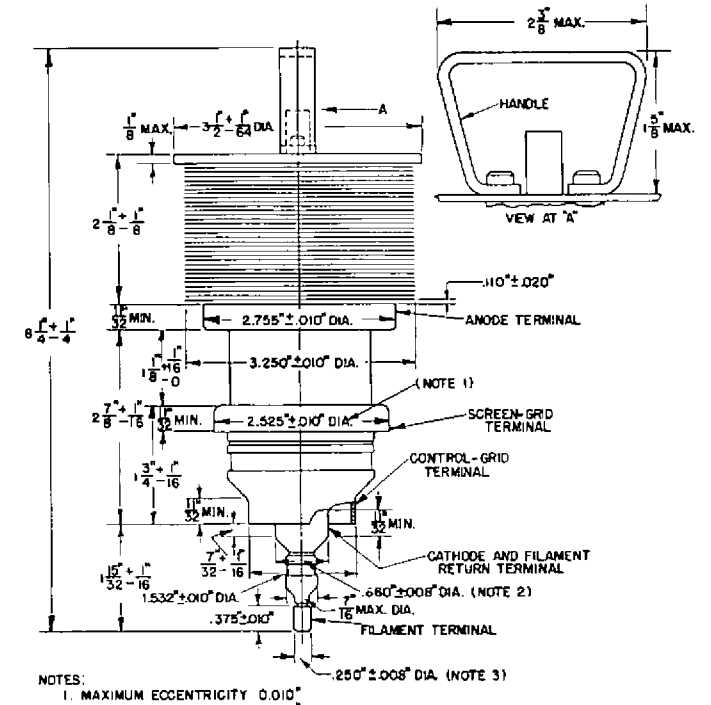
ƒ Represents maximum useable cathode current (plate current plus current to each grid) for any condition of operation.

ƒƒ Measured with a 6-inch diameter flat metal disk attached to the screen-grid ring. Control grid connected to the screen grid.

ƒƒƒ Output capacitance measured between anode and screen grid. Control grid connected directly to screen grid.

ƒƒƒƒ The volume of cooling air indicated for the various seals is approximate only. Distribution of cooling air will vary with the cavity configuration about the tube. For most satisfactory operation the maximum temperature of any point on the tube shall be below 200 C.

◊ Useful power output including power transferred from driver stage.



π The carrier of the driver modulated 100 percent.

ø Modulation essentially negative may be used if the positive peak of the envelope does not exceed 115 percent of the carrier conditions.

Δ Total anode power output including power transferred from driver stage.

GL-6958

IGNITRON

The GL-6958 is a double-grid ignitron designed for industrial rectifier or inverter applications where it will operate at peak inverse voltages as high as 4000 volts. In such applications six tubes will supply 3000 kilowatts at voltages of 1800 or 3600 volts d-c, depending upon the circuit used.

A particular design feature of this tube makes it especially suitable for use where voltage control by phase retard is in excess of the amounts usually required. In addition, the tube features a coaxial cathode current return which reduces magnetic fields caused by the tube currents.

MAXIMUM RATINGS

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Heater Positive with Respect to Cathode	50	Volts
Heater Negative with Respect to Cathode	50	Volts
Envelope Temperature§	250	C
Grid-Circuit Resistance	0.01	Megohms

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

GENERAL ELECTRIC

Supersedes ET-T1488 dated 3-58 and 10-59

CHARACTERISTICS AND TYPICAL OPERATION

AVERAGE CHARACTERISTICS

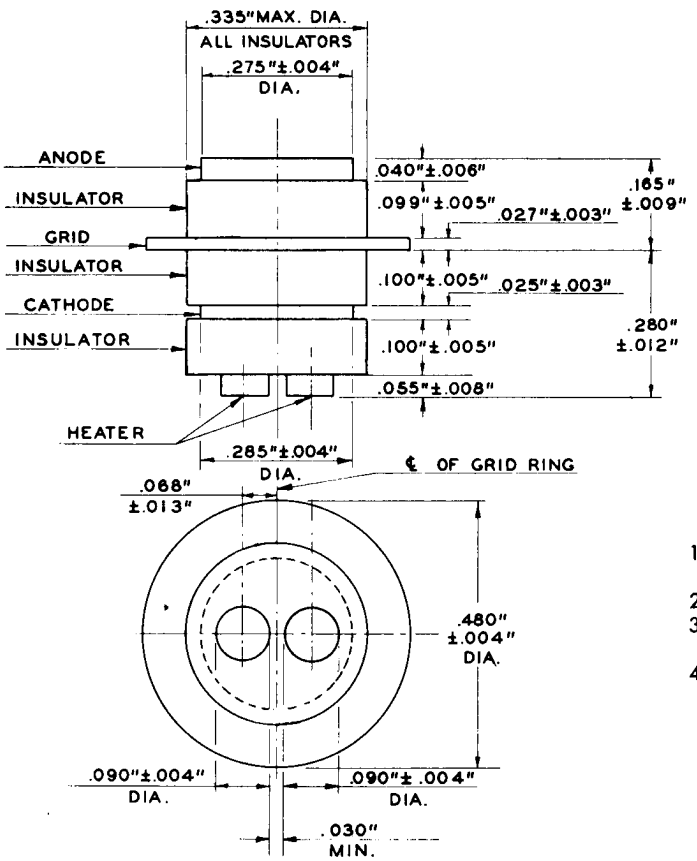
Plate Supply Voltage	250	Volts
Resistor in Plate Circuit (bypassed)	18000	Ohms
Cathode-Bias Resistor	82	Ohms
Amplification Factor	90	
Plate Resistance, approximate	9000	Ohms
Transconductance	10000	Micromhos
Plate Current	6.5	Milliamperes
Grid Voltage, approximate Gm = 50 Micromhos	−5	Volts

GROUNDED-GRID AMPLIFIER—450 MEGACYCLES

Plate Supply Voltage¶	250	Volts
Resistor in Plate Circuit (bypassed)¶	18000	Ohms
Cathode-Bias Resistor	82	Ohms
Plate Current	6.5	Milliamperes
Bandwidth, approximate	7.5	Megacycles
Power Gain, approximate	14.5	Decibels
Noise Figure (Measured with power-matched input, using argon lamp noise source), approximate	5.5	Decibels

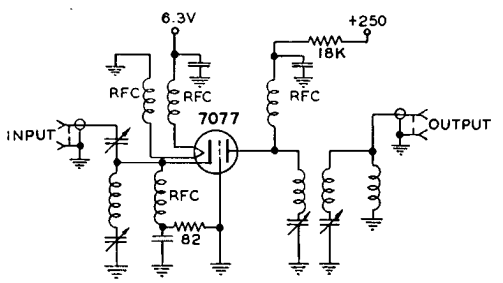
FOOTNOTES

* The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.



† Heater current of a bogey tube at Ef = 6.3 volts.

‡ Measured using a grounded adapter that provides shielding between external terminals of tube.



§ Operation below the rated maximum envelope temperature is recommended for applications requiring the longest possible tube life. The 7077 is also capable of operation at envelope temperatures much higher than the rated maximum values. For specific recommendations concerning higher temperature operation, contact your General Electric tube sales representative.

¶ Lower supply voltage and a lower value of resistor may be used in the plate circuit with some sacrifice in uniformity of performance.

OUTLINE DRAWING

TYPICAL GROUNDED-GRID AMPLIFIER CIRCUIT USING THE 7077

1—Maximum eccentricity of anode, grid, and cathode 0.005" from center line.
2—Maximum eccentricity of insulators 0.010" from center line.
3—Center line of grid ring used as reference line for horizontal tolerances.
4—Bottom surface of grid ring used as reference line for vertical tolerances.

INITIAL CHARACTERISTICS LIMITS

	Min.	Bogey	Max.	
Heater Current				
Ef = 6.3 volts	222	240	258	Milliamperes
Plate Current				
Ef = 6.3 volts, Ebb = 250 volts, R_L = 18000 ohms, Rk = 82 ohms (bypassed)	4.5	6.5	8.5	Milliamperes
Transconductance				
Ef = 6.3 volts, Ebb = 250 volts, R_L = 18000 ohms (bypassed), Rk = 82 ohms (bypassed)	7000	10000	13000	Micromhos
Transconductance Change with Heater Voltage				
Difference between Transconductance measured at Ef = 6.3 and Ef = 6.0 volts (other conditions the same) expressed as a percentage	....	.....	20	Percent
Amplification Factor				
Ef = 6.3 volts, Ebb = 250 volts, R_L = 18000 ohms (bypassed), Rk = 82 ohms (bypassed)	65	90	115	
Interelectrode Capacitances				
Grid to Plate: (g to p)	0.84	1.00	1.16	Picofarads
Input: g to (h+k)	1.25	1.70	2.15	Picofarads
Output: p to (h+k)	0.004	0.010	0.016	Picofarads
Heater to Cathode: (h to k)	0.80	1.10	1.40	Picofarads
Heater-Cathode Leakage Current				
Ef = 6.3 volts, Ehk = 100 volts				
Heater Positive with Respect to Cathode	....	.....	20	Microamperes
Heater Negative with Respect to Cathode	....	.....	20	Microamperes
Interelectrode Leakage Resistance				
Ef = 6.3 volts, Polarity of applied d-c interelectrode voltage is such that no cathode emission results.				
Grid to All at 100 volts d-c	100	.....	.....	Megohms
Plate to All at 300 volts d-c	100	.....	.....	Megohms
Grid Emission Current				
Ef = 7.0 volts, Ebb = 250 volts, Ecc = −20 volts, Rk = 82 ohms (bypassed), Rg = 0.1 meg, R_L = 18000 ohms (bypassed)	....	.....	2.0	Microamperes

SPECIAL PERFORMANCE TESTS

	Min.	Bogey	Max.	
Noise Figure				
Ef = 6.3 volts, Ebb = 250 volts, Rk = 82 ohms, R_L = 18000 ohms, F = 450 mc	....	5.5	6.6	Decibels
Noise Figure at Reduced Heater Voltage				
Ef = 6.0 volts, Ebb = 250 volts, Rk = 82 ohms, R_L = 18000 ohms, F = 450 mc	....	.....	8.1	Decibels
Power Gain				
Ef = 6.3 volts, Ebb = 250 volts, Rk = 82 ohms, R_L = 18000 ohms, F = 450 mc	12.5	14.5	.....	Decibels

SPECIAL PERFORMANCE TESTS (Continued)
