BASING DIAGRAM

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

MAXIMUM RATINGS (Cont'd)

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

AVERAGE CHARACTERISTICS

Tube Voltage Drop, approximate		
Ib = 7.0 Milliamperes DC	100	Volts

X-RADIATION RATING¶

X-radiation, maximum	0.5	mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 0.5 mR/hr at any time throughout their useful life, when operated within the maximum ratings, including heater voltage, specified on this data sheet.

This X-radiation maximum rating is based on data obtained with the use of the Victoreen 440 RF survey meter with a 3 3/8 inch aperture. X-radiation is measured with the face of the meter at a distance of 4 3/4 inches from the external surface of the tube. This rating information is not necessarily applicable when a different radiation measuring instrument or aperture is used.

Operation of the 1AY2-A outside of the Absolute-Maximum Ratings indicated may damage the tube and/or result in either temporary or permanent changes in the X-radiation characteristics of the tube. Equipment design must be such that these Absolute-Maximum Ratings are not exceeded.

The above X-radiation characteristics are measured in accordance with JEDEC Publication No. 67, "Recommended Practice for Measurement of X-Radiation from Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73, "Recommended Practice for Quality Control of X-Radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein.

WARNING

X-RADIATION

Operation of the 1AY2-A outside of the Absolute-Maximum Ratings indicated may produce soft X-rays above 0.5 milliroentgens per hour which may constitute a health hazard on prolonged exposure at close range unless the tube is adequately shielded. Equipment design must provide required shielding.

Precautions must be exercised during the servicing of equipment employing the 1AY2-A to assure that the high voltage is adjusted to the recommended value and that any shielding components are replaced to their intended positions before the equipment is operated.

SHOCK HAZARD

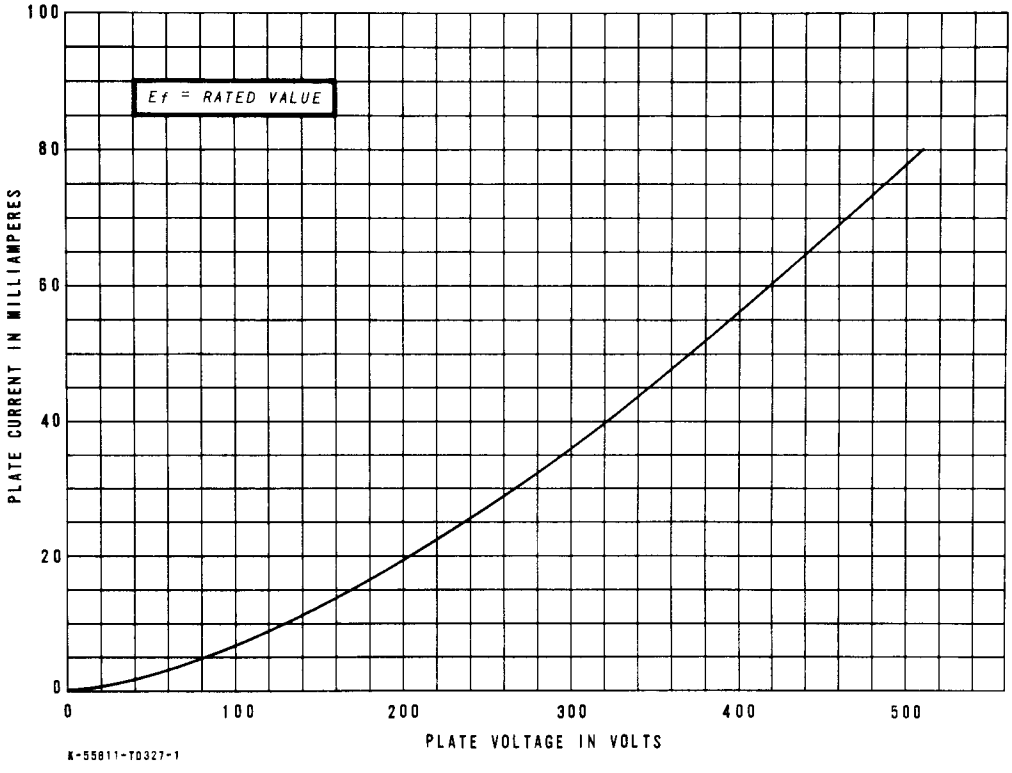
The high voltages at which the 1AY2-A is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and for the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 1AY2-A in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN.

NOTES

* The equipment designer should design the equipment so that filament voltage is centered at the specified bogey value, with filament supply variations restricted to maintain filament voltage within the specified tolerance.



‡ Filament current of a bogey tube at Ef = 1.25 volts.

§ Without external shield.

¶ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

¢ CAUTION - Operation of this tube for an extended period of time with the filament voltage above the absolute maximum rated value of 1.45 volts may result in the production of X-radiation in excess of the maximum rated limit of 0.5 mR/hr.

DESCRIPTION AND RATING

TR TUBE GL-1B24-A

The GL-1B24-A is a gas switching tube of the integral-cavity tunable type for use in simple duplexers in pulsed microwave circuits which do not require that the short circuit in the tube have a fixed electrical position. The tube operates to decouple effectively the receiver from a common transmitting and receiving antenna during a transmission period. The operational band is from 8490 to 9600 megacycles.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

AVERAGE CHARACTERISTICS

Tube Voltage Drop, approximate Ib = 7.0 Milliamperes ..... 100 Volts

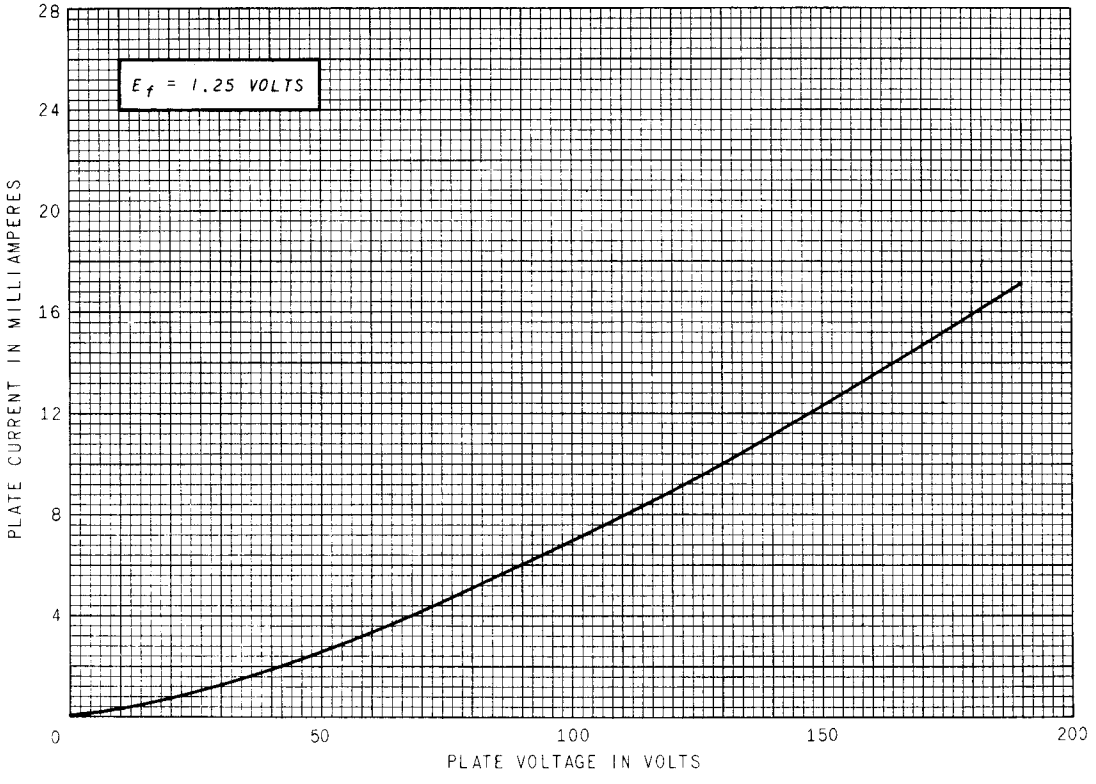
* The equipment designer should design the equipment so that filament voltage is centered at the specified bogey value, with filament supply variations restricted to maintain filament voltage within the specified tolerance.

† Filament current of a bogey tube at Ef = 1.25 volts.

‡ Without external shield.

§ Socket terminals 1, 3, 4, 5, 6, and 8 may be connected to terminal 7 or to a corona shield which connects to terminal 7. Terminals 4 and 6 may be used as tie points for components at or near filament potential.

¶ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.



Note: The voltages employed in some television receivers and other high-voltage equipment are sufficiently high that high-voltage rectifier tubes may produce soft x-rays which can constitute a health hazard unless such tubes are adequately shielded. The need for this precaution should be considered in equipment design. Relatively simple shielding should prove adequate.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Ib = 7.0 Milliamperes ..... 80 Volts

X-RADIATION RATING♦

MAXIMUM RATED OPERATING CONDITIONS

Total DC and Peak Inverse Voltage	Maximum X-Radiation Output
§18 KV	0.5 mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 0.5 mR/hr at any time throughout their useful life, when operated within the maximum ratings, including filament voltage, specified on this data sheet.

This X-radiation maximum rating is based on the use of the Victoreen 440 RF/C survey meter as the standard instrument for X-radiation measurement. X-radiation is measured with the plastic spacer of the 440 RF/C survey meter at a distance of four (4) inches from the external surface of the tube under test. This rating information is not necessarily applicable when a different radiation measuring instrument is used.

Operation at voltages outside of the Absolute-Maximum Ratings will cause permanent damage to the tube resulting in short life and/or catastrophic failure. Any tube known to have operated above 18 KV peak inverse voltage and/or 1.45 V filament voltage should be replaced with the latest version of the same tube type.

The X-radiation characteristics are measured in accordance with JEDEC Publication No. 67A, "Recommended Practice for Measurement of X-Radiation from Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73A, "Recommended Practice for Quality Control of X-Radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein, except as noted under "X-Radiation Characteristics."

X-RADIATION CHARACTERISTICS

EQUIPMENT MISADJUSTMENT AND/OR CIRCUIT FAILURE MODE OPERATION

The 1BC2-B will produce varying levels of X-radiation depending upon operating conditions. Based on known attenuation factors of tube construction materials and accumulated sample test data taken initially and during life test, X-radiation output is not expected to exceed the indicated value under equipment misadjustment and/or circuit failure mode operations of plate and filament voltage listed below.

Total DC and Peak Inverse Voltage	Maximum Filament Voltage	Maximum Expected X-Radiation Output
§20 KV	§1.8 V	0.5 mR/hr

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated with total DC and peak inverse voltage above 20 KV, or with filament voltage above 1.8 V.

Operation at voltages outside of the Absolute-Maximum Ratings will cause permanent damage to the tube resulting in short life and/or catastrophic failure. Any tube known to have operated above 18 KV peak inverse voltage and/or 1.45 V filament voltage should be replaced with the latest version of the same tube type.

WARNING

X-RADIATION

X-radiation in excess of 0.5 mR/hr may constitute a health hazard on prolonged exposure at close range. Therefore, equipment design must provide for adequate shielding.

Operation of the 1BC2-B with total DC and peak inverse voltage greater than 20 KV may result in radiation in excess of the "Maximum Expected X-Radiation Output" listed under "X-Radiation Characteristics."

Precautions must be exercised during the servicing of the equipment employing the 1BC2-B to assure that the high voltage is adjusted to the recommended value and that any shielding components are replaced to their intended positions before the equipment is operated.

SHOCK HAZARD

The high voltages at which the 1BC2-B is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and in the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 1BC2-B in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN.

NOTES

* The equipment designer should design the equipment so that filament voltage is centered at the specified bogey value, with filament supply variations restricted to maintain filament voltage within the specified tolerance.

• Filament current of a bogey tube at Ef = 1.25 volts.

▲ Without external shield.

– May be used as a tie-point for filament dropping resistor or may be connected to filament. Do not connect to any other circuits.

♦ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

CAUTION - Operation at voltages outside of the Absolute-Maximum Ratings will cause permanent damage to the tube resulting in short life and or catastrophic failure. Any tube known to have operated above 18 KV peak inverse voltage and 1.45 V filament voltage should be replaced with the latest version of the same type.

MAXIMUM RATINGS (Cont'd)

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

AVERAGE CHARACTERISTICS

Tube Voltage Drop, approximate		
Ib = 7.0 Milliamperes	225	Volts

X-RADIATION RATING♦

X-radiation, maximum	0.5	mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 0.5 mR/hr at any time throughout their useful life, when operated within the maximum ratings, including filament voltage, specified on this data sheet.

This X-radiation maximum rating is based on the use of the Victoreen 440 RF/C survey meter as the standard instrument for X-radiation measurement. X-radiation is measured with the plastic spacer of the 440 RF/C survey meter at a distance of four (4) inches from the external surface of the tube under test. This rating information is not necessarily applicable when a different radiation measuring instrument is used.

Operation of the 1BY2-A outside of the Absolute-Maximum Ratings indicated may damage the tube and/or result in either temporary or permanent changes in the X-radiation characteristics of the tube. Equipment design must be such that these Absolute-Maximum Ratings are not exceeded.

The above X-radiation characteristics are measured in accordance with JEDEC Publication No. 67A, "Recommended Practice for Measurement of X-radiation from Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73A, "Recommended Practice for Quality Control of X-radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein.

WARNING

X-RADIATION

Operation of the 1BY2-A outside of the Absolute-Maximum Ratings indicated may produce soft X-rays above 0.5 milliroentgens per hour which may constitute a health hazard on prolonged exposure at close range unless the tube is adequately shielded. Equipment design must provide required shielding.

Precautions must be exercised during the servicing of the equipment employing the 1BY2-A to assure that the high voltage is adjusted to the recommended value and that any shielding components are replaced to their intended positions before the equipment is operated.

SHOCK HAZARD

The high voltages at which the 1BY2-A is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and for the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 1BY2-A in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

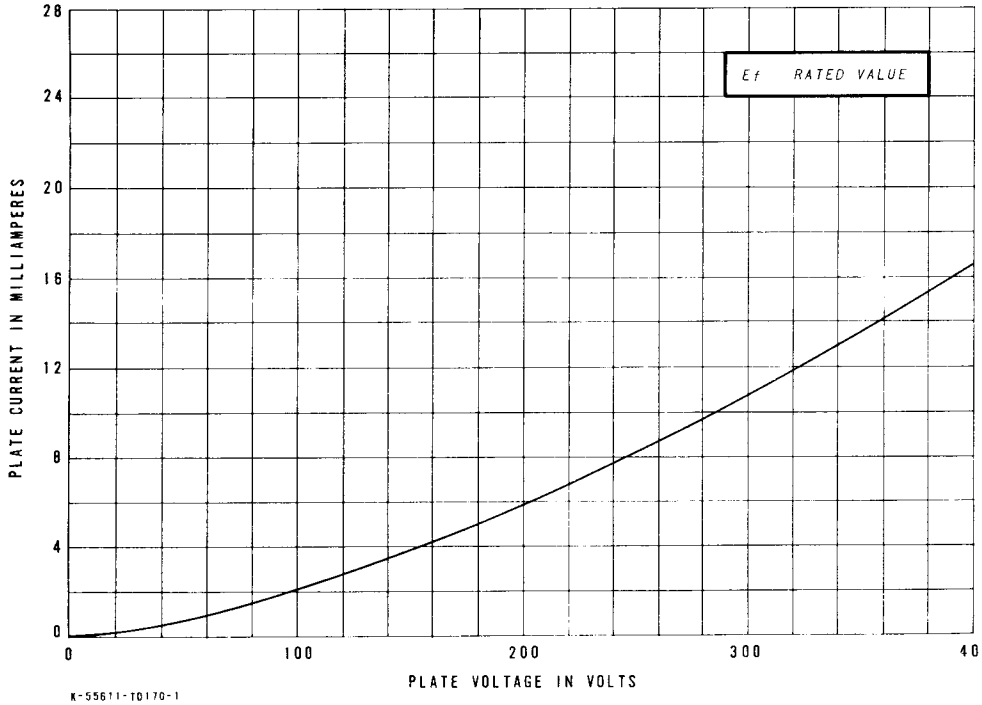
THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN.

NOTES

★ The equipment designer should design the equipment so that filament voltage is centered at the specified bogey value, with filament supply variations restricted to maintain filament voltage within the specified tolerance.

● Filament current of a bogey tube at Ef = 1.25 volts.

▲ Without external shield.



♦ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

§ **CAUTION** - Operation of this tube for an extended period of time with the filament voltage above the absolute maximum rated value of 1.45 volts may result in the production of X-radiation in excess of the maximum rated limit of 0.5 mR/hr.

⊕ Socket terminals 3, 4, 7 and 10 may be used as tie points for components at or near filament potential.

MAXIMUM RATINGS (Cont'd)

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

AVERAGE CHARACTERISTICS

Tube Voltage Drop, approximate
Ib = 7.0 Milliamperes ..... 225 Volts

X-RADIATION RATING §

MAXIMUM RATED OPERATING CONDITIONS

Total DC and Peak Inverse Voltage	Maximum X-Radiation Output
⊕26 KV	0.5 mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 0.5 mR/hr at any time throughout their useful life, when operated within the maximum ratings, including filament voltage, specified on this data sheet.

This X-radiation maximum rating is based on the use of the Victoreen 440 RF/C survey meter as the standard instrument for X-radiation measurement. X-radiation is measured with the plastic spacer of the 440 RF/C survey meter at a distance of four (4) inches from the external surface of the tube under test. This rating information is not necessarily applicable when a different radiation measuring instrument is used.

Operation at voltages outside of the Absolute-Maximum Ratings will cause permanent damage to the tube resulting in short life and/or catastrophic failure. Any tube known to have operated above 26 KV peak inverse voltage and/or 1.45 V filament voltage should be replaced with the latest version of the same tube type.

The X-radiation characteristics are measured in accordance with JEDEC Publication No. 67A, "Recommended Practice for Measurement of X-Radiation from Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73A, "Recommended Practice for Quality Control of X-Radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein, except as noted under "X-Radiation Characteristics."

X-RADIATION CHARACTERISTICS

EQUIPMENT MISADJUSTMENT AND/OR CIRCUIT FAILURE MODE OPERATION

The 1DG3-A will produce varying levels of X-radiation depending upon operating conditions. Based on known attenuation factors of tube construction materials and accumulated sample test data taken initially and during life test, X-radiation output is not expected to exceed the indicated value under equipment misadjustment and/or circuit failure mode operations of plate and filament voltage listed below.

Total DC and Peak Inverse Voltage	Maximum Filament Voltage	Maximum Expected X-Radiation Output
⊕30 KV	⊕2.0 V	0.5 mR/hr

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated with total DC and peak inverse voltage above 30 KV, or with filament voltage above 2.0 V.

Operation at voltages outside of the Absolute-Maximum Ratings will cause permanent damage to the tube resulting in short life and or catastrophic failure. Any tube known to have operated above 26 KV peak inverse voltage and/or 1.45 V filament voltage should be replaced with the latest version of the same tube type.

WARNING

X-RADIATION

X-radiation in excess of 0.5 mR/hr may constitute a health hazard on prolonged exposure at close range. Therefore, equipment design must provide for adequate shielding.

Operation of the 1DG3-A with total DC and peak inverse voltage greater than 30 KV may result in radiation in excess of the "Maximum Expected X-Radiation Output" listed under "X-Radiation Characteristics".

Precautions must be exercised during the servicing of the equipment employing the 1DG3-A to assure that the high voltage is adjusted to the recommended value and that any shielding components are replaced to their intended positions before the equipment is operated.

SHOCK HAZARD

The high voltages at which the 1DG3-A is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and in the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 1DG3-A in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN.

NOTES

★ The equipment designer should design the equipment so that filament voltage is centered at the specified bogey value, with filament supply variations restricted to maintain filament voltage within the specified tolerance.

● Filament current of a bogey tube at Ef = 1.25 volts.

▲ Without external shield.

♦ May be used as a tie-point for filament dropping resistor or may be connected to filament. Do not connect to any other circuits.

§ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

⊕ **CAUTION** -Operation at voltages outside of the Absolute-Maximum Ratings will cause permanent damage to the tube resulting in short life and/or catastrophic failure. Any tube known to have operated above 26 KV peak inverse voltage and 1.45 V filament voltage should be replaced with the latest version of the same type.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

1DN5

DIODE-PENTODE

DESCRIPTION AND RATING

The 1DN5 is a miniature, filamentary, single-diode, remote-cutoff pentode intended for use as a combined detector, audio-amplifier, and automatic volume-control tube in battery-operated receivers. As a result of its remote-cutoff characteristic, automatic-volume-control voltage may be applied to the pentode section of the 1DN5. By introducing AVC to the audio-amplifier stage, an improved over-all AVC response of the receiver can be achieved.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

AVERAGE CHARACTERISTICS

Tube Voltage Drop, approximate		
Ib = 7.0 Milliamperes DC	100	Volts

X-RADIATION RATING¶

X-radiation, maximum	0.5	mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 0.5 mR/hr at any time throughout their useful life, when operated within the maximum ratings, including heater voltage, specified on this data sheet.

This X-radiation maximum rating is based on data obtained with the use of the Victoreen 440 RF survey meter with a 3 3/8 inch aperture. X-radiation is measured with the face of the meter at a distance of 4 3/4 inches from the external surface of the tube. This rating information is not necessarily applicable when a different radiation measuring instrument or aperture is used.

Operation of the 1G3-GTA outside of the Absolute-Maximum Ratings indicated may damage the tube and/or result in either temporary or permanent changes in the X-radiation characteristics of the tube. Equipment design must be such that these Absolute-Maximum Ratings are not exceeded.

The above X-radiation characteristics are measured in accordance with JEDEC Publication No. 67, "Recommended Practice for Measurement of X-Radiation from Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73, "Recommended Practice for Quality Control of X-Radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein.

WARNING

X-RADIATION

Operation of the 1G3-GTA outside of the Absolute-Maximum Ratings indicated may produce soft X-rays above 0.5 milliroentgens per hour which may constitute a health hazard on prolonged exposure at close range unless the tube is adequately shielded. Equipment design must provide required shielding.

Precautions must be exercised during the servicing of equipment employing the 1G3-GTA to assure that the high voltage is adjusted to the recommended value and that any shielding components are replaced to their intended positions before the equipment is operated.

SHOCK HAZARD

The high voltages at which the 1G3-GTA is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and for the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 1G3-GTA in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

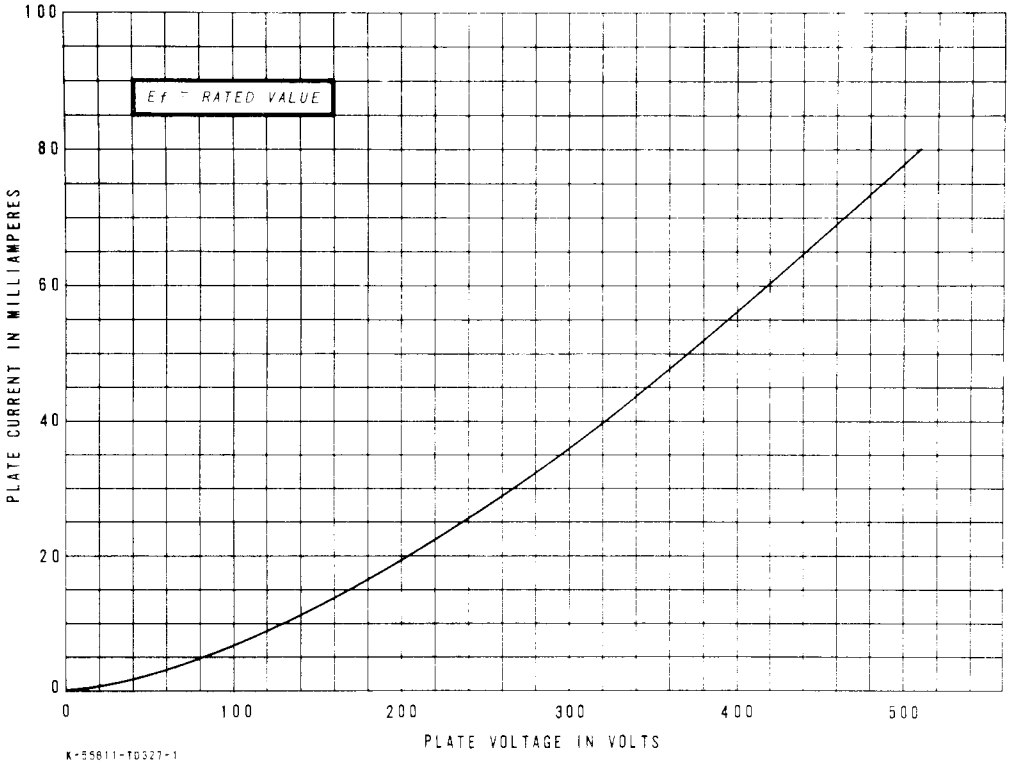
THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN.

NOTES

* The equipment designer should design the equipment so that filament voltage is centered at the specified bogey value, with filament supply variations restricted to maintain filament voltage within the specified tolerance.

‡ Filament current of a bogey tube at Ef = 1.25 volts.

§ Without external shield.



Δ Pins 4 and 6 are omitted on Bases B6-120 and B6-253. Socket terminals 4 and 6 may be used as tie points for components at or near filament potential.

¶ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

¢ CAUTION - Operation of this tube for an extended period of time with the filament voltage above the absolute maximum rated value of 1.45 volts may result in the production of X-radiation in excess of the maximum rated limit of 0.5 mR/hr.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

AVERAGE CHARACTERISTICS

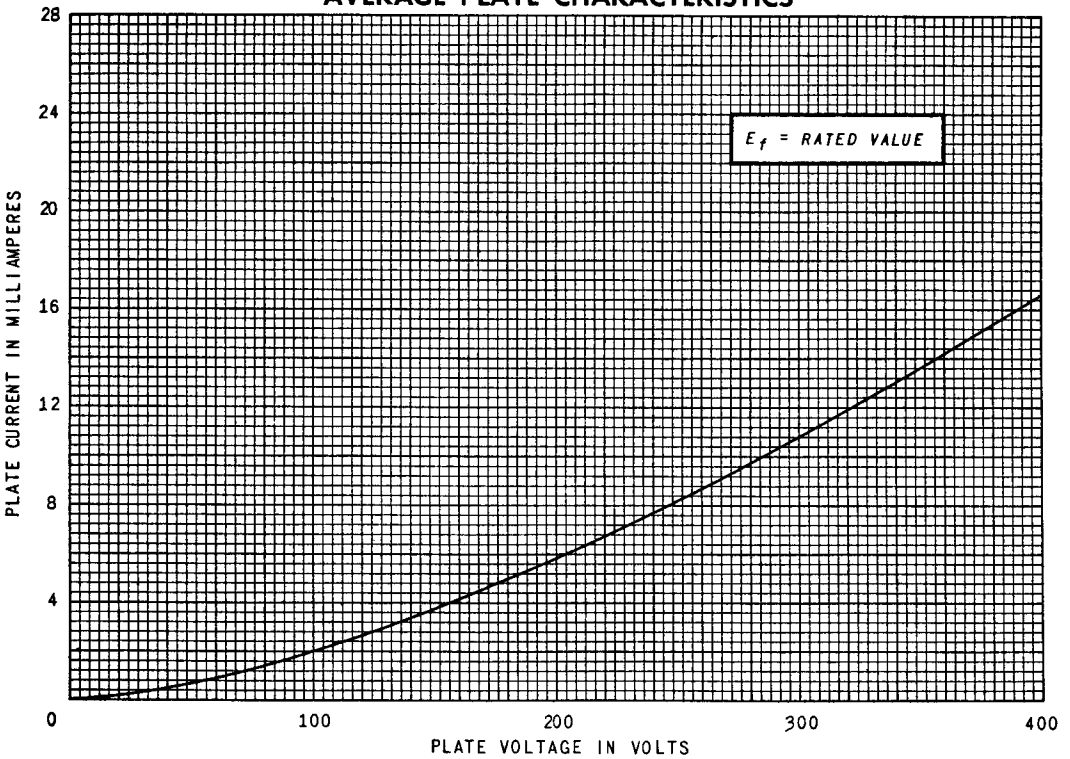
Tube Voltage Drop, approximate Ib = 7.0 Milliamperes DC. . . . . 225 Volts

* The equipment designer should design the equipment so that filament voltage is centered at the specified bogey value, with filament supply variations restricted to maintain filament voltage within the specified tolerance.

† Filament current of a bogey tube at Ef = 1.25 volts.

‡ Without external shield.

§ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.



Note: The voltages employed in some television receivers and other high-voltage equipment are sufficiently high that high-voltage rectifier tubes may produce soft x-rays which can constitute a health hazard unless such tubes are adequately shielded. The need for this precaution should be considered in equipment design. Relatively simple shielding should prove adequate.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

FOR TV HIGH-VOLTAGE RECTIFIER APPLICATIONS

1K3-A

■ MONOCHROME TYPE ■ 22000 VOLTS DC ■ 0.5 MILLIAMPERES DC ■ X-RADIATION RATING

The 1K3-A is a filamentary diode designed for use in television receivers as the high-voltage rectifier to supply power to the anode of the television picture tube. It is primarily intended for use in flyback types of power supplies.

Features of the 1K3-A include built-in X-radiation shielding and additional design and specification controls for the reduction of X-radiation output.

MAXIMUM RATINGS (Cont'd)

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

AVERAGE CHARACTERISTICS

Tube Voltage Drop, approximate		
Ib = 7.0 Milliamperes DC	225	Volts

X-RADIATION RATING*

X-radiation, maximum	0.5	mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 0.5 mR/hr at any time throughout their useful life, when operated within the maximum ratings, including heater voltage, specified on this data sheet.

This X-radiation maximum rating is based on data obtained with the use of the Victoreen 440 RF survey meter with a 3 3/8 inch aperture. X-radiation is measured with the face of the meter at a distance of 4 3/4 inches from the external surface of the tube. This rating information is not necessarily applicable when a different radiation measuring instrument or aperture is used.

Operation of the 1K3-A outside of the Absolute-Maximum Ratings indicated may damage the tube and/or result in either temporary or permanent changes in the X-radiation characteristics of the tube. Equipment design must be such that these Absolute-Maximum Ratings are not exceeded.

The above X-radiation characteristics are measured in accordance with JEDEC Publication No. 67, "Recommended Practice for Measurement of X-Radiation from Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73, "Recommended Practice for Quality Control of X-Radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein.

WARNING

X-RADIATION

Operation of the 1K3-A outside of the Absolute-Maximum Ratings indicated may produce soft X-rays above 0.5 milliroentgens per hour which may constitute a health hazard on prolonged exposure at close range unless the tube is adequately shielded. Equipment design must provide required shielding.

Precautions must be exercised during the servicing of equipment employing the 1K3-A to assure that the high voltage is adjusted to the recommended value and that any shielding components are replaced to their intended positions before the equipment is operated.

SHOCK HAZARD

The high voltages at which the 1K3-A is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and for the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 1K3-A in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

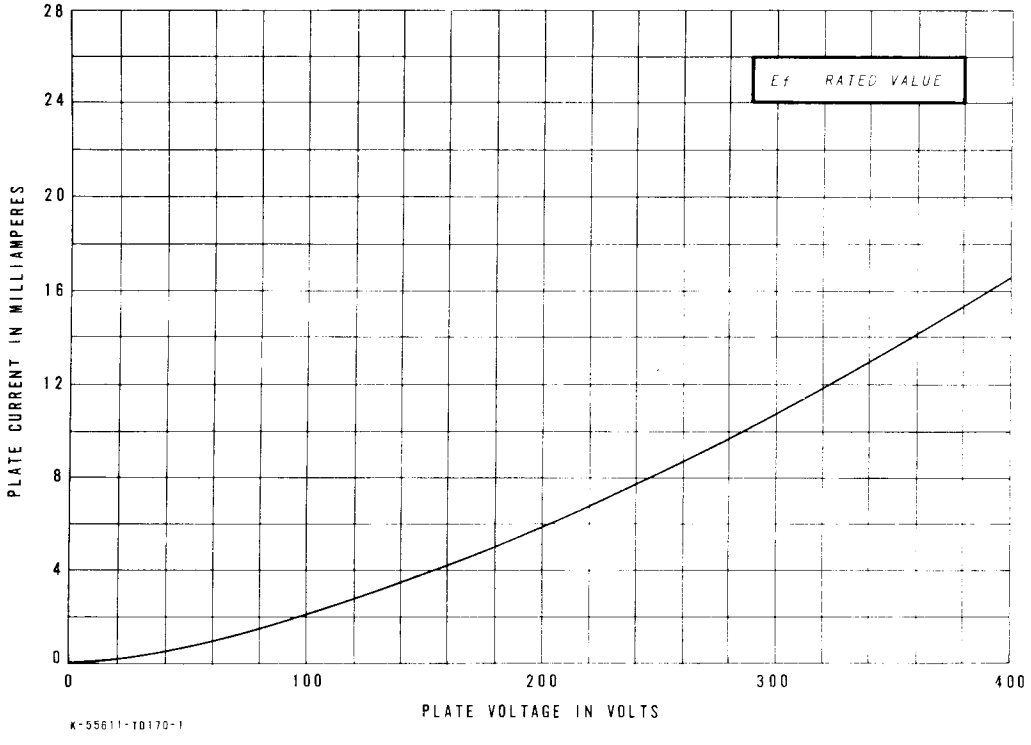
THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN.

NOTES

* The equipment designer should design the equipment so that filament voltage is centered at the specified bogey value, with filament supply variations restricted to maintain filament voltage within the specified tolerance.

‡ Filament current of a bogey tube at Ef = 1.25 volts.

§ Without external shield.



Δ Pins 4 and 6 are omitted on Bases B6-120 and B6-253. Socket terminals 4 and 6 may be used as tie points for components at or near filament potential.

¶ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

¢ CAUTION - Operation of this tube for an extended period of time with the filament voltage above the absolute maximum rated value of 1.45 volts may result in the production of X-radiation in excess of the maximum rated limit of 0.5 mR/hr.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

Beacon Reference Cavity

DESCRIPTION AND RATING

REFERENCE CAVITY GL-1Q26-A

The GL-1Q26-A is a fixed-frequency, transmission-type, vacuum-sealed reference cavity for use as a frequency-determining reference at 9280 megacycles.

Particular advantages of this cavity are its ability to operate over a wide temperature range, from -40 to +100 C, with a change of only 0.3 megacycle in resonant frequency and the fact that it can be used in a pressurized system.

MAXIMUM RATINGS (Cont'd)

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

AVERAGE CHARACTERISTICS

Tube Voltage Drop, approximate		
Ib = 7.0 Milliamperes	60	Volts

X-RADIATION RATING♦

X-radiation, maximum	25	mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 25 mR/hr at any time throughout their useful life, when operated within the maximum ratings, including heater voltage, specified on this data sheet.

This X-radiation maximum rating is based on the use of the Victoreen 440 RF/C survey meter as the standard instrument for X-radiation measurement. X-radiation is measured with the plastic spacer of the 440 RF/C survey meter at a distance of four (4) inches from the external surface of the tube under test. This rating information is not necessarily applicable when a different radiation measuring instrument is used.

Operation of the 2AS2-A outside of the Absolute-Maximum Ratings indicated may damage the tube and/or result in either temporary or permanent changes in the X-radiation characteristics of the tube. Equipment design must be such that these Absolute-Maximum Ratings are not exceeded.

The above X-radiation characteristics are measured in accordance with JEDEC Publication No. 67A, "Recommended Practice for Measurement of X-radiation from Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73A, "Recommended Practice for Quality Control of X-radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein.

WARNING

X-RADIATION

The high voltages associated with the 2AS2-A result in production of X-radiation which may constitute a health hazard on prolonged exposure at close range unless the tube is adequately shielded. Equipment design must provide for this shielding.

Precautions must be exercised during the servicing of equipment employing the 2AS2-A to assure that the high voltage is adjusted to the recommended value and that any shielding components are replaced to their intended positions before the equipment is operated.

SHOCK HAZARD

The high voltages at which the 2AS2-A is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and for the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 2AS2-A in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

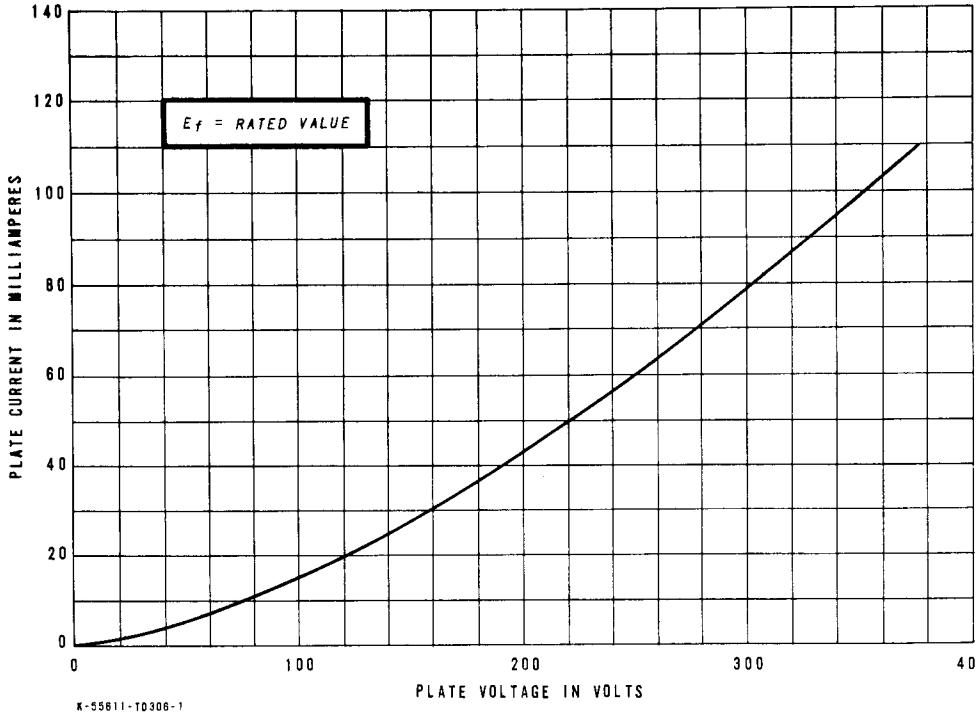
THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN.

NOTES

★ The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

● Heater current of a bogey tube at Ef = 2.5 volts.

▲ Without external shield.



♦ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

§ **CAUTION** - Operation of this tube for an extended period of time with the heater voltage above the absolute maximum rated value of 2.9 volts may result in the production of X-radiation in excess of the maximum rated limit of 25 mR/hr.

⊕ Socket terminals 4, 7, and 10 may be used as tie points for components at or near heater potential.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

Electronic TUBES

2B3

DIODE

FOR TV HIGH-VOLTAGE RECTIFIER APPLICATIONS

DESCRIPTION AND RATING

The 2B3 is a filamentary diode designed for use in television receivers as the high-voltage rectifier to supply power to the anode of the television picture tube. It is intended primarily for use in flyback types of power supplies. Primarily, the 2B3 differs from the 1B3-GT by incorporating higher filament ratings which in many cases will permit the tube to be operated directly from the flyback transformer without the use of a filament dropping resistor.

GENERAL

Design-Maximum Ratings are the limiting values, expressed with respect to bogie tubes, at which satisfactory tube life can be expected to occur. In order to obtain satisfactory circuit performance, therefore, the equipment designer must establish the circuit design so that no design-maximum value is exceeded with a bogie tube under the worst probable operating conditions with respect to the combined effect of supply-voltage variation, equipment component variation, equipment control adjustment, load variation, and any other variation associated with the equipment or the environment of the equipment.

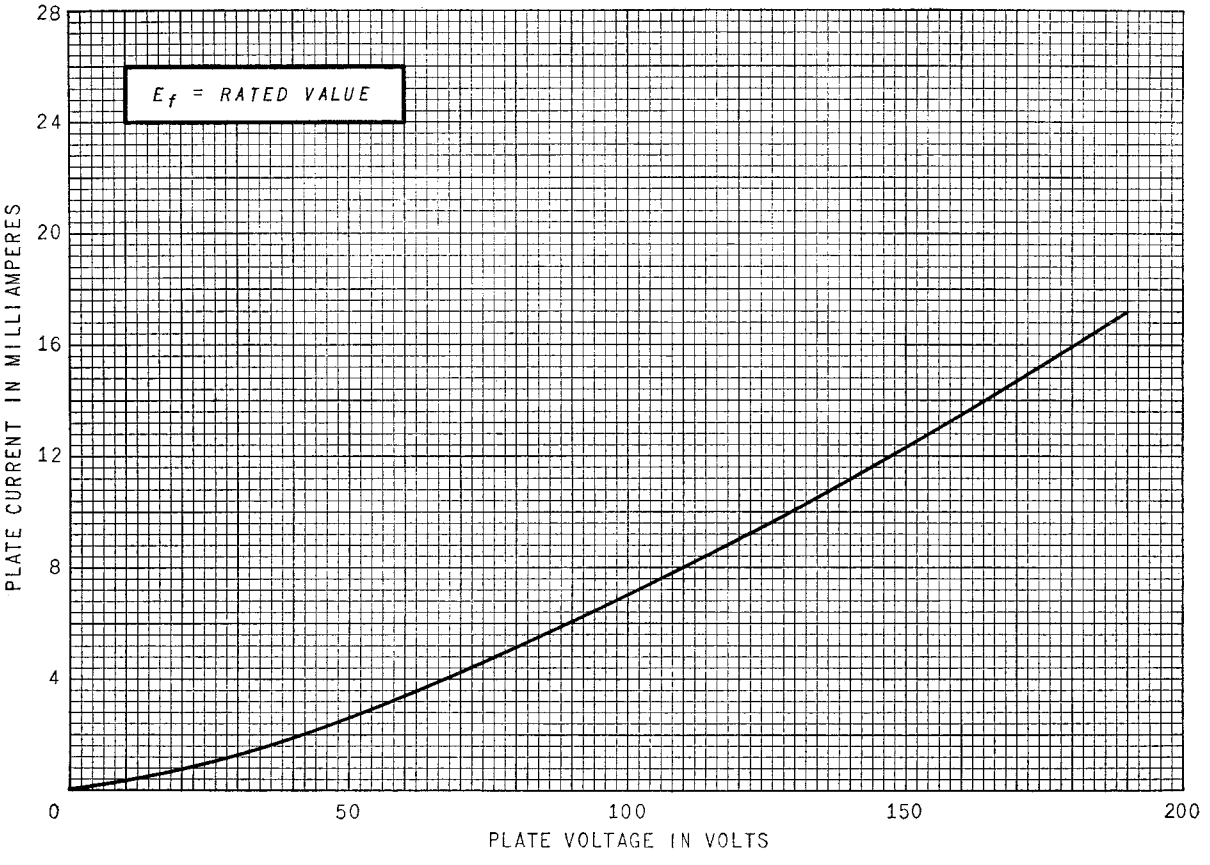
PHYSICAL DIMENSIONS

AVERAGE CHARACTERISTICS

Tube Voltage Drop, approximate
Ib = 7.0 Milliamperes DC . . . . . 100 Volts



* Under no circumstances should the filament voltage be less than 1.5 volts or more than 2.0 volts.

† Without external shield.

§ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

Note: The voltages employed in some television receivers and other high-voltage equipment are sufficiently high that high-voltage rectifier tubes may produce soft x-rays which can constitute a health hazard unless such tubes are adequately shielded. The need for this precaution should be considered in equipment design. Relatively simple shielding should prove adequate.

Compactron Diode

2BU2

FOR TV HIGH-VOLTAGE RECTIFIER APPLICATIONS

■ COLOR TV TYPE ■ 24000 VOLTS DC ■ 1.5 MILLIAMPERES DC ■ X-RADIATION RATING

The 2BU2 is a heater-cathode type diode designed for use in color television receivers as the high-voltage rectifier to supply power to the anode of the picture tube.

The 2BU2 features built-in X-radiation shielding and additional design and specification controls for the reduction of X-radiation output.

MAXIMUM RATINGS (Cont'd)

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

AVERAGE CHARACTERISTICS

Tube Voltage Drop, approximate Ib = 7.0 Milliamperes	60	Volts

X-RADIATION RATING♦

X-radiation, maximum	0.5	mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 0.5 mR/hr at any time throughout their useful life, when operated within the maximum ratings, including heater voltage, specified on this data sheet.

This X-radiation maximum rating is based on the use of the Victoreen 440 RF/C survey meter as the standard instrument for X-radiation measurement. X-radiation is measured with the plastic spacer of the 440 RF/C survey meter at a distance of four (4) inches from the external surface of the tube under test. This rating information is not necessarily applicable when a different radiation measuring instrument is used.

Operation of the 2BU2 outside of the Absolute-Maximum Ratings indicated may damage the tube and/or result in either temporary or permanent changes in the X-radiation characteristics of the tube. Equipment design must be such that these Absolute-Maximum Ratings are not exceeded.

The above X-radiation characteristics are measured in accordance with JEDEC Publication No. 67A, "Recommended Practice for Measurement of X-radiation from Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73A, "Recommended Practice for Quality Control of X-radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein.

WARNING

X-RADIATION

Operation of the 2BU2 outside of the Absolute-Maximum Ratings indicated may produce soft X-rays above 0.5 milliroentgens per hour which may constitute a health hazard on prolonged exposure at close range unless the tube is adequately shielded. Equipment design must provide required shielding.

Precautions must be exercised during the servicing of the equipment employing the 2BU2 to assure that the high voltage is adjusted to the recommended value and that any shielding components are replaced to their intended positions before the equipment is operated.

SHOCK HAZARD

The high voltages at which the 2BU2 is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and for the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 2BU2 in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

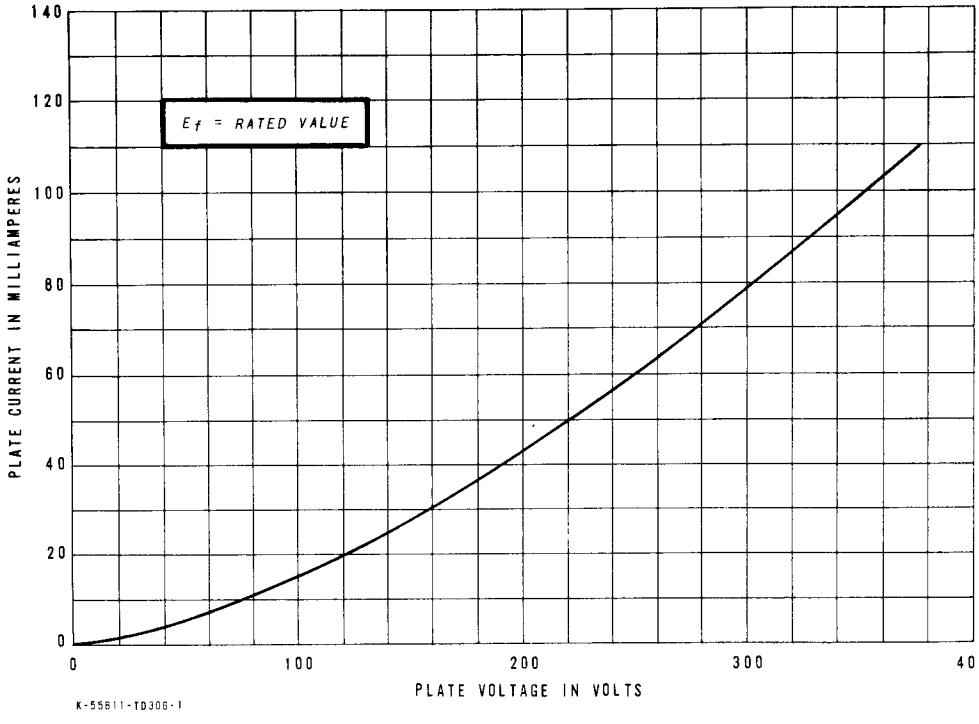
THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN.

NOTES

★ The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

● Heater current of a bogey tube at Ef = 2.5 volts.

▲ Without external shield.



⊕ Socket terminals 4, 10 and 11 may be used as tie points for components at or near heater potential.

♦ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

§ **CAUTION** - Operation of this tube for an extended period of time with the heater voltage above the absolute maximum rated value of 2.9 volts may result in the production of X-radiation in excess of the maximum rated limit of 0.5mR/hr.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

PLANAR TRIODE

DESCRIPTION AND RATING

FOR GROUNDED-GRID OSCILLATOR AND AMPLIFIER SERVICE

Metal and Ceramic
High Transconductance
Low Interelectrode Capacitances
Shock Resistant

100 Watts Plate Dissipation

The 2C39-B is a metal-and-ceramic, high-mu triode designed for use as a grounded-grid oscillator or amplifier at frequencies as high as 2500 megacycles.

Features of the 2C39-B include planar electrode construction, high plate dissipation capability, excellent electrode isolation, low radio-frequency losses, high transconductance, and low interelectrode capacitances.

* The equipment designer should design the equipment so that heater voltage is centered at some value within the range of 4.5 to 6.3 volts. Heater voltage variations about the center value should be kept as small as practical and should not, in any case, exceed ±5%. The optimum center value of heater voltage depends on the cathode current and on other parameters of circuit design and operation. For specific recommendations, contact your General Electric tube sales representative.

† Heater current of a bogey tube at Ef = 6.3 volts.

‡ Measured in a special shielded socket.

§ Modulation essentially negative may be used if the positive peak of the audio-frequency envelope does not exceed 115 percent of the carrier conditions.

⁂ Where long life and reliable operation are important, lower envelope temperatures should be used.

¶ For modulation factors less than 1.0, a higher d-c plate voltage may be used if the sum of the peak positive audio voltage and the d-c plate voltage does not exceed 1200 volts.

2C40-A
PLANAR TRIODE

DESCRIPTION AND RATING

The 2C40-A is a triode of lighthouse construction designed for use as a CW oscillator, radio-frequency amplifier, or plate-pulsed oscillator at frequencies as high as 3370 megacycles.

The radio-frequency cathode connection is made through a disk-type capacitor which is incorporated in the tube. This results in a low-impedance radio-frequency path from the cathode to the external circuit.

The envelope construction results in low losses, provides convenient electrode contact surfaces, and enables the tube to fit easily into coaxial circuits.

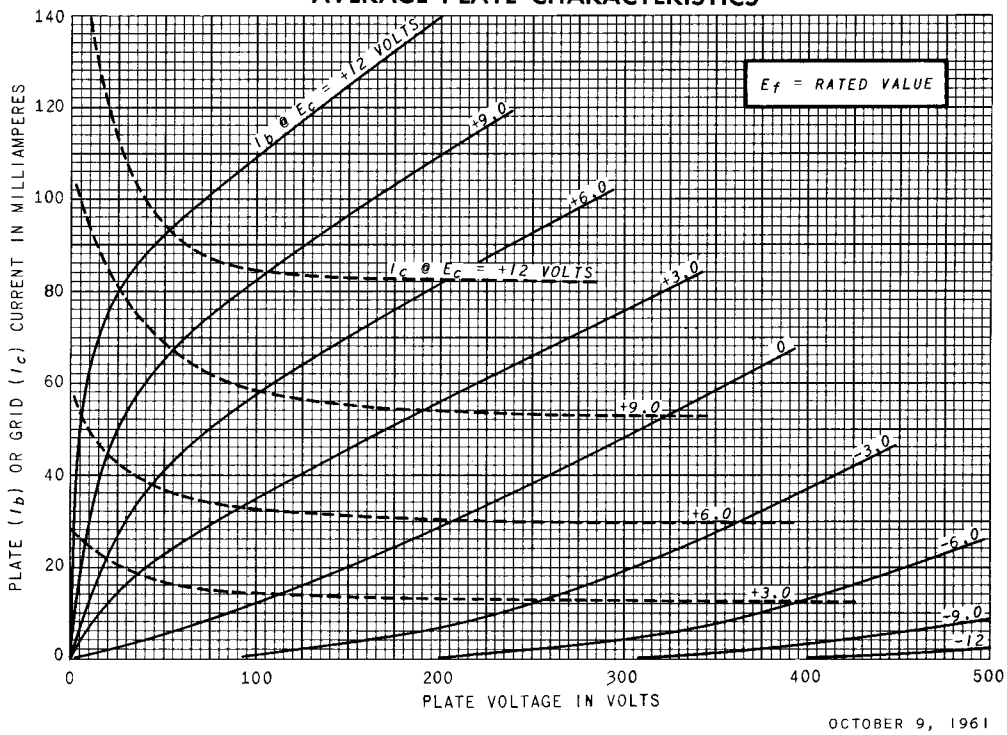
* The equipment designer should design the equipment so that the heater voltage is centered at a value suitable for the application. Heater voltage variations about the center value should be kept as small as practical and should not, in any case, exceed ±5%. The optimum center value of heater voltage depends on the cathode current and on the other parameters of circuit design and operation. For specific recommendations, contact your General Electric tube sales representative.

† Heater current of a bogey tube at Ef = 6.3 volts.

‡ Without external shield.



Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

Diode

2CN3-B

FOR TV HIGH-VOLTAGE RECTIFIER APPLICATIONS

- COLOR TV TYPE
- 30000 VOLTS DC
- 2.2 MILLIAMPERES DC
- DIFFUSION BONDED CATHODE
- X-RADIATION RATING

The 2CN3-B is a heater-cathode type diode designed for use in color television receivers as the high-voltage rectifier to supply power to the anode of the picture tube. Features of the tube include a diffusion bonded cathode coating to minimize reverse emission failures, and X-radiation controls.

The diffusion bonded cathode coating practically eliminates one of the major failure mechanisms in high-voltage rectifiers, which is back-emission from the anode due to emissive particles being pulled from the cathode by the very high electrostatic field.

The 2CN3-B features built-in X-radiation shielding and additional design and specification controls for the reduction of X-radiation output.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

AVERAGE CHARACTERISTICS

Tube Voltage Drop, approximate		
Ib = 7.0 Milliamperes	60	Volts

X-RADIATION RATING¶

X-radiation, maximum	25	mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 25 mR/hr at any time throughout their useful life, when operated within the maximum ratings, including heater voltage, specified on this data sheet.

This X-radiation maximum rating is based on data obtained with the use of the Victoreen RF survey meter with a 3 3/8 inch aperture. X-radiation is measured with the face of the meter at a distance of 4 3/4 inches from the external surface of the tube. This rating information is not necessarily applicable when a different radiation measuring instrument or aperture is used.

Operation of the 2CN3-B outside of the Absolute-Maximum Ratings indicated may damage the tube and/or result in either temporary or permanent changes in the X-radiation characteristics of the tube. Equipment design must be such that these Absolute-Maximum Ratings are not exceeded.

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein.

X-RADIATION CHARACTERISTICS

The 2CN3-B will produce varying levels of X-radiation depending on operating conditions. Based on known attenuation factors of tube construction materials and accumulated sample test data taken initially and during life test, X-radiation output is not expected to exceed the maximum expected values indicated below for the different values of total DC and peak inverse voltage, with all other operating conditions remaining constant.

TOTAL DC AND PEAK INVERSE VOLTAGE	MAXIMUM EXPECTED X-RADIATION OUTPUT
38 KV (30 KV Maximum DC Component)	25.0 mR/hr
33 KV (27 KV Maximum DC Component)	3.0 mR/hr
30 KV (25 KV Maximum DC Component)	0.5 mR/hr

The above X-radiation characteristics are measured in accordance with JEDEC Publication No. 67, "Recommended Practice for Measurement of X-Radiation from Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73, "Recommended Practice for Quality Control of X-Radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

WARNING

X-RADIATION

The high voltages associated with the 2CN3-B result in production of X-radiation which may constitute a health hazard on prolonged exposure at close range unless the tube is adequately shielded. Equipment design must provide for this shielding.

Precautions must be exercised during the servicing of equipment employing the 2CN3-B to assure that the high voltage is adjusted to the recommended value and that any shielding components are replaced to their intended positions before the equipment is operated.

SHOCK HAZARD

The high voltages at which the 2CN3-B is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and for the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 2CN3-B in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

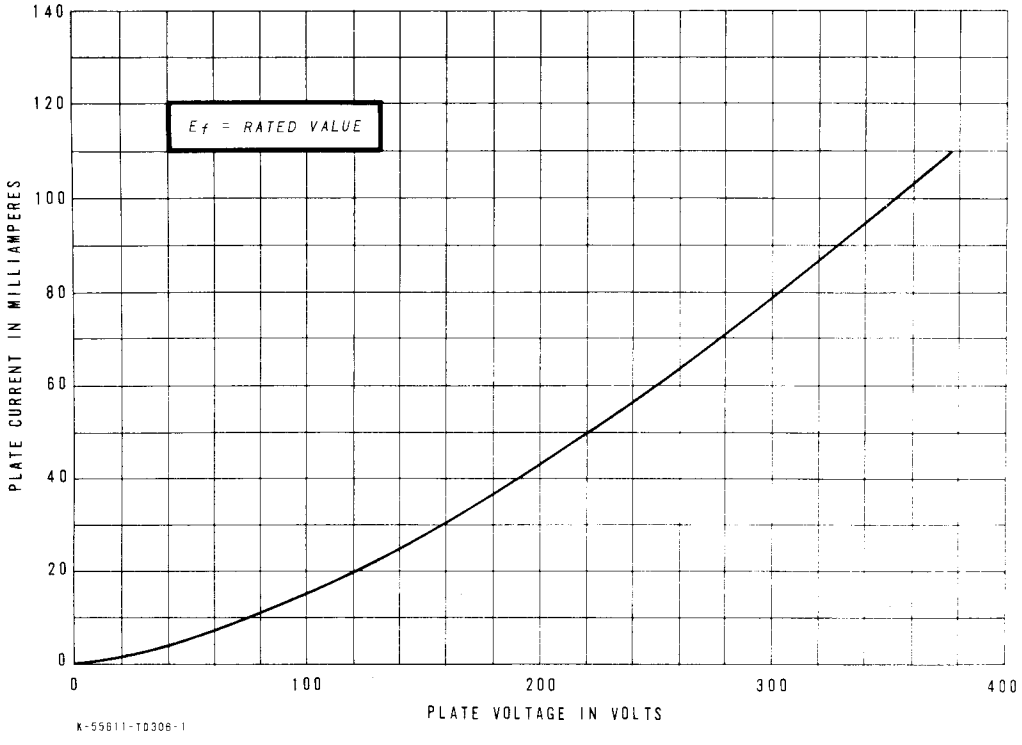
THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN

NOTES

* The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

‡ Heater current of a bogey tube at Ef = 1.8 volts.

§ Without external shield.



Socket terminals 4 and 6 may be used as tie points for components at or near heater potential.

¶ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

¢ CAUTION - Operation of this tube for an extended period of time with the heater voltage above the absolute maximum rated value of 2.0 volts may result in the production of X-radiation in excess of the maximum rated limit of 25 mR/hr.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

MAXIMUM RATINGS (Cont'd)

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

AVERAGE CHARACTERISTICS

Tube Voltage Drop, approximate		
Ib = 7.0 Milliamperes	60	Volts

X-RADIATION RATING¶

X-radiation, maximum.	25	mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 25 mR/hr at any time throughout their useful life, when operated within the maximum ratings, including heater voltage, specified on this data sheet.

This X-radiation maximum rating is based on data obtained with the use of the Victoreen 440 RF survey meter with a 3 3/8 inch aperture. X-radiation is measured with the face of the meter at a distance of 4 3/4 inches from the external surface of the tube. This rating information is not necessarily applicable when a different radiation measuring instrument or aperture is used.

Operation of the 3A3-C outside of the Absolute-Maximum Ratings indicated may damage the tube and/or result in either temporary or permanent changes in the X-radiation characteristics of the tube. Equipment design must be such that these Absolute-Maximum Ratings are not exceeded.

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein.

X-RADIATION CHARACTERISTICS

The 3A3-C will produce varying levels of X-radiation depending on operating conditions. Based on known attenuation factors of tube construction materials and accumulated sample test data taken initially and during life test, X-radiation output is not expected to exceed the maximum expected values indicated below for the different values of total DC and peak inverse voltage, with all other operating conditions remaining constant.

TOTAL DC AND PEAK INVERSE VOLTAGE	MAXIMUM EXPECTED X-RADIATION OUTPUT	
38 KV (30 KV Maximum DC Component)	25.0	mR/hr
33 KV (27 KV Maximum DC Component)	3.0	mR/hr
30 KV (25 KV Maximum DC Component)	0.5	mR/hr

The above X-radiation characteristics are measured in accordance with JEDEC Publication No. 67, "Recommended Practice for Measurement of X-Radiation from Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73, "Recommended Practice for Quality Control of X-Radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

WARNING

X-RADIATION

The high voltages associated with the 3A3-C result in production of X-radiation which may constitute a health hazard on prolonged exposure at close range unless the tube is adequately shielded. Equipment design must provide for this shielding.

Precautions must be exercised during the servicing of equipment employing the 3A3-C to assure that the high voltage is adjusted to the recommended value and that any shielding components are replaced to their intended positions before the equipment is operated.

SHOCK HAZARD

The high voltages at which the 3A3-C is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and for the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 3A3-C in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

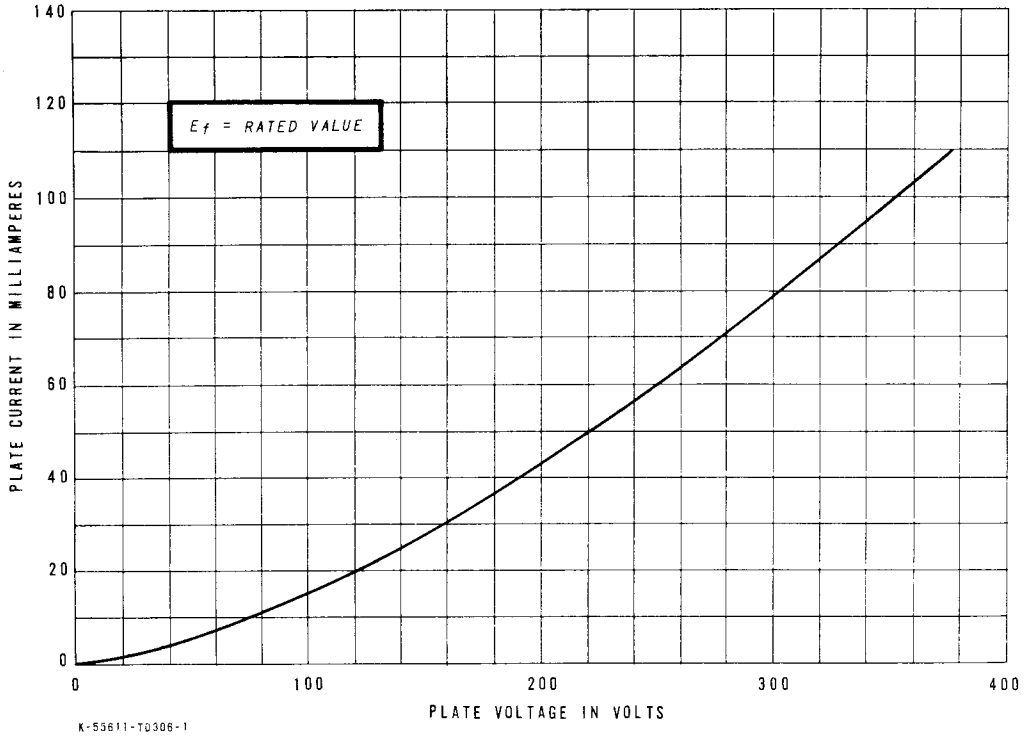
THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN.

NOTES

* The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

‡ Heater current of a bogey tube at Ef = 3.15 volts.

§ Without external shield.



¶ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

CAUTION - Operation of this tube for an extended period of time with the heater voltage above the absolute maximum rated value of 3.65 volts may result in the production of X-radiation in excess of the maximum rated limit of 25 mR/hr.

Δ Pins 4 and 6 are omitted on Base B6-253. Socket terminals 4 and 6 may be used as tie points for components at or near heater potential.

MAXIMUM RATINGS

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

FOOTNOTES

* The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

† Heater current of a bogey tube at Ef = 3.15 volts.

‡ Without external shield.

§ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

Note: The voltages employed in some television receivers and other high-voltage equipment are sufficiently high that high-voltage rectifier tubes may produce soft x-rays which can consititute a health hazard unless such tubes are adequately shielded. The need for this precaution should be considered in equipment design. Relatively simple shielding should prove adequate.

3AT2-B

FOR TV HIGH-VOLTAGE RECTIFIER APPLICATIONS

■ COLOR TV TYPE ■ 30000 VOLTS DC ■ 1.7 MILLIAMPERES DC ■ X-RADIATION RATING

The 3AT2-B is a heater-cathode type diode designed for use in color television receivers as the high-voltage rectifier to supply power to the anode of the picture tube. It is primarily intended for use in flyback types of power supplies.

The 3AT2-B voltage and current ratings are consistent with the requirements of present day color television applications.

The 3AT2-B features built-in X-radiation shielding and additional design and specifications controls for the reduction of X-radiation output.

MAXIMUM RATINGS (Cont'd)

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

AVERAGE CHARACTERISTICS

Tube Voltage Drop, approximate Ib = 7.0 Milliamperes	60	Volts

X-RADIATION RATING⊕

X-radiation, maximum	25	mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 25 mR/hr at any time throughout their useful life, when operated within the maximum ratings, including heater voltage, specified on this data sheet.

This X-radiation maximum rating is based on the use of the Victoreen 440 RF/C survey meter as the standard instrument for X-radiation measurement. X-radiation is measured with the plastic spacer of the 440 RF/C survey meter at a distance of four (4) inches from the external surface of the tube under test. This rating information is not necessarily applicable when a different radiation measuring instrument is used.

Operation of the 3AT2-B outside of the Absolute-Maximum Ratings indicated may damage the tube and/or result in either temporary or permanent changes in the X-radiation characteristics of the tube. Equipment design must be such that these Absolute-Maximum Ratings are not exceeded.

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein.

X-RADIATION CHARACTERISTICS

The 3AT2-B will produce varying levels of X-radiation depending on operating conditions. Based on known attenuation factors of tube construction materials and accumulated sample test data taken initially and during life test, X-radiation output is not expected to exceed the maximum expected values indicated below for the different values of total DC and peak inverse voltage, with all other operating conditions remaining constant.

TOTAL DC AND PEAK INVERSE VOLTAGE	MAXIMUM EXPECTED X-RADIATION OUTPUT	
38 KV (30 KV Maximum DC Component)	25.0	mR/hr
33 KV (27 KV Maximum DC Component)	3.0	mR/hr
30 KV (25 KV Maximum DC Component)	0.5	mR/hr

The above X-radiation characteristics are measured in accordance with JEDEC Publication No. 67A, "Recommended Practice for Measurement of X-radiation from Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73A, "Recommended Practice for Quality Control of X-radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

WARNING

X-RADIATION

The high voltages associated with the 3AT2-B result in production of X-radiation which may constitute a health hazard on prolonged exposure at close range unless the tube is adequately shielded. Equipment design must provide for this shielding.

Precautions must be exercised during the servicing of equipment employing the 3AT2-B to assure that the high voltage is adjusted to the recommended value and that any shielding components are replaced to their intended positions before the equipment is operated.

SHOCK HAZARD

The high voltages at which the 3AT2-B is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and for the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 3AT2-B in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

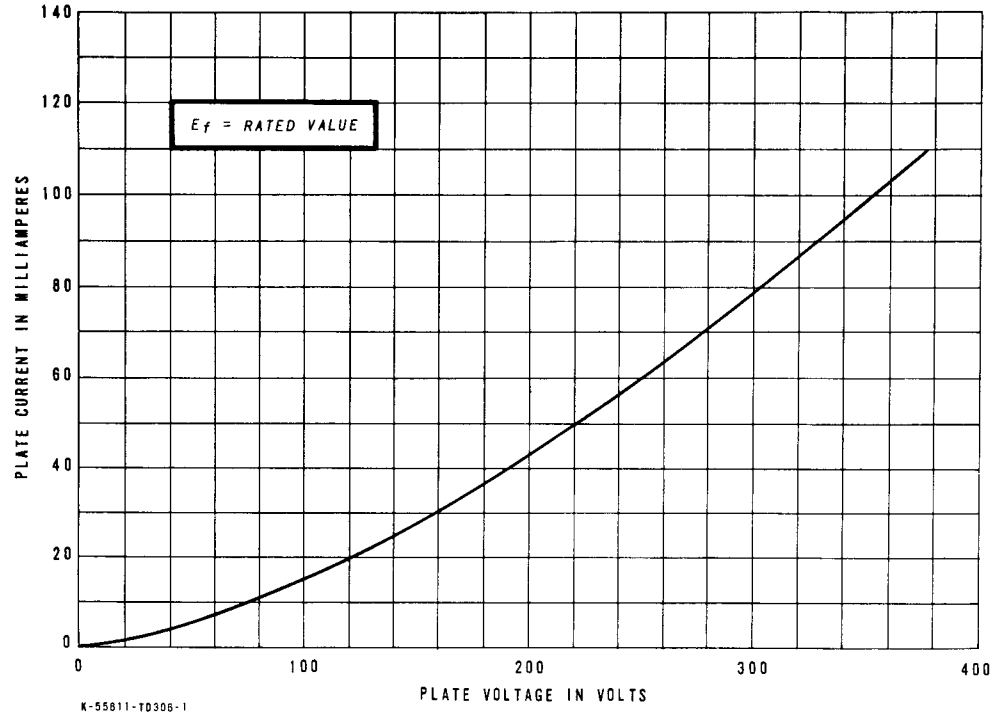
THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN.

NOTES

★ The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

● Heater current of a bogey tube at Ef = 3.15 volts.

♦ Without external shield.



▲ Socket terminals 4, 7, and 10 may be used as tie points for components at or near heater potential.

⊕ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

§ **CAUTION** - Operation of this tube for an extended period of time with the heater voltage above the absolute maximum rated value of 3.65 volts may result in the production of X-radiation in excess of the maximum rated limit of 25 mR/hr.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

3BN2-A

FOR TV HIGH-VOLTAGE RECTIFIER APPLICATIONS

- COLOR TV TYPE
- 27000 VOLTS DC
- 1.7 MILLIAMPERES DC
- DIFFUSION BONDED CATHODE
- FAST WARM-UP
- X-RADIATION RATING

The 3BN2-A is a heater-cathode type diode designed for use in color television receivers as the high-voltage rectifier to supply power to the anode of the picture tube. Features of the tube include fast operational warm-up, a diffusion bonded cathode coating to minimize reverse emission failures, and X-radiation controls.

The diffusion bonded cathode coating practically eliminates one of the major failure mechanisms in high-voltage rectifiers, which is back-emission from the anode due to emissive particles being pulled from the cathode by the very high electrostatic field.

The 3BN2-A features built-in X-radiation shielding and additional design and specification controls for the reduction of X-radiation output.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

AVERAGE CHARACTERISTICS

Tube Voltage Drop, approximate		
Ib = 7.0 Milliamperes	70	Volts

X-RADIATION RATING⊕

X-radiation, maximum	25	mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 25 mR/hr at any time throughout their useful life, when operated within the maximum ratings, including heater voltage, specified on this data sheet.

This X-radiation maximum rating is based on the use of the Victoreen 440 RF/C survey meter as the standard instrument for X-radiation measurement. X-radiation is measured with the plastic spacer of the 440 RF/C survey meter at a distance of four (4) inches from the external surface of the tube under test. This rating information is not necessarily applicable when a different radiation measuring instrument is used.

Operation of the **3BW2** outside of the Absolute-Maximum Ratings indicated may damage the tube and/or result in either temporary or permanent changes in the X-radiation characteristics of the tube. Equipment design must be such that these Absolute-Maximum Ratings are not exceeded.

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein.

X-RADIATION CHARACTERISTICS

The 3BW2 will produce varying levels of X-radiation depending on operating conditions. Based on known attenuation factors of tube construction materials and accumulated sample test data taken initially and during life test, X-radiation output is not expected to exceed the maximum expected values indicated below for the different values of total DC and peak inverse voltage, with all other operating conditions remaining constant.

TOTAL DC AND PEAK INVERSE VOLTAGE	MAXIMUM EXPECTED X-RADIATION OUTPUT	
38 KV (30 KV Maximum DC Component)	25.0	mR/hr
33 KV (27 KV Maximum DC Component)	3.0	mR/hr
30 KV (25 KV Maximum DC Component)	0.5	mR/hr

The above X-radiation characteristics are measured in accordance with JEDEC Publication No. 67A, "Recommended Practice for Measurement of X-radiation from Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73A, "Recommended Practice for Quality Control of X-radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

WARNING

X-RADIATION

The high voltages associated with the 3BW2 result in production of X-radiation which may constitute a health hazard on prolonged exposure at close range unless the tube is adequately shielded. Equipment design must provide for this shielding.

Precautions must be exercised during the servicing of equipment employing the 3BW2 to assure that the high voltage is adjusted to the recommended value and that any shielding components are replaced to their intended positions before the equipment is operated.

SHOCK HAZARD

The high voltages at which the 3BW2 is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and for the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 3BW2 in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

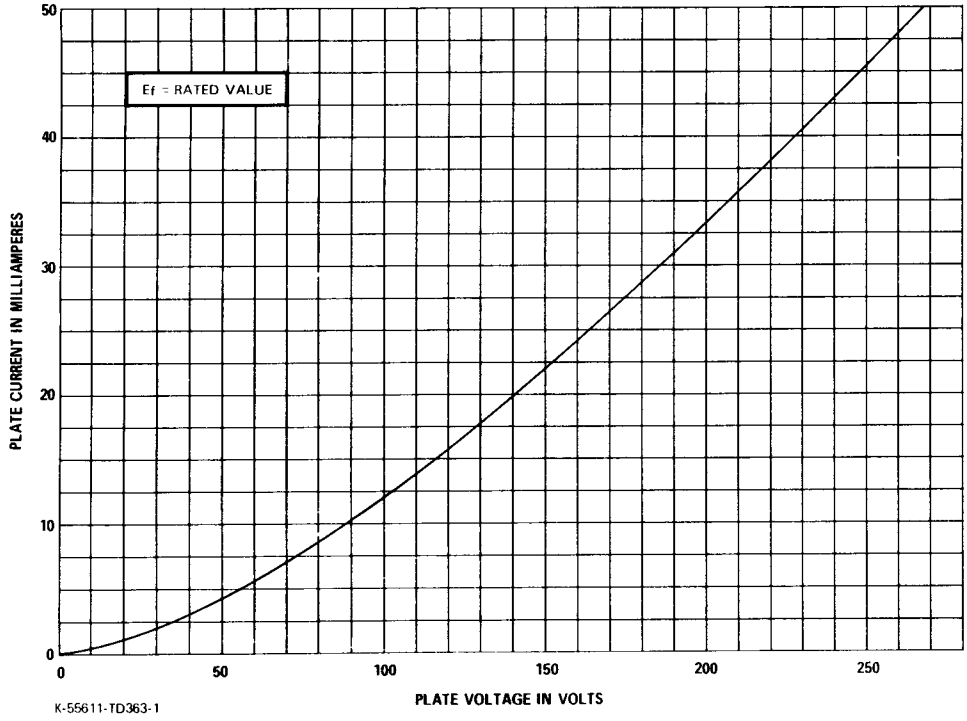
THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN.

NOTES

★ The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

● Heater current of a bogey tube at Ef = 3.15 volts.

♦ Without external shield.



▲ Socket terminals 4 and 10 may be used as tie points for components at or near heater potential.

⊕ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

§ **CAUTION** - Operation of this tube for an extended period of time with the heater voltage above the absolute maximum rated value of 3.65 volts may result in the production of X-radiation in excess of the maximum rated limit of 25 mR/hr.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

X-RADIATION RATING¶

X-radiation, maximum	25	mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 25 mR/hr at any time throughout their useful life, when operated within the maximum ratings, including heater voltage, specified on this data sheet.

This X-radiation maximum rating is based on data obtained with the use of the Victoreen 440 RF survey meter with a 3 3/8 inch aperture. X-radiation is measured with the face of the meter at a distance of 4 3/4 inches from the external surface of the tube. This rating information is not necessarily applicable when a different radiation measuring instrument or aperture is used.

Operation of the 3CN3-B outside of the Absolute-Maximum Ratings indicated may damage the tube and/or result in either temporary or permanent changes in the X-radiation characteristics of the tube. Equipment design must be such that these Absolute-Maximum Ratings are not exceeded.

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein.

X-RADIATION CHARACTERISTICS

The 3CN3-B will produce varying levels of X-radiation depending on operating conditions. Based on known attenuation factors of tube construction materials and accumulated sample test data taken initially and during life test, X-radiation output is not expected to exceed the maximum expected values indicated below for the different values of total DC and peak inverse voltage, with all other operating conditions remaining constant.

TOTAL DC AND PEAK INVERSE VOLTAGE	MAXIMUM EXPECTED X-RADIATION OUTPUT
38 KV (30 KV Maximum DC Component)	25.0 mR/hr
33 KV (27 KV Maximum DC Component)	3.0 mR/hr
30 KV (25 KV Maximum DC Component)	0.5 mR/hr

The above X-radiation characteristics are measured in accordance with JEDEC Publication No. 67, "Recommended Practice for Measurement of X-Radiation from Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73, "Recommended Practice for Quality Control of X-Radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

WARNING

X-RADIATION

The high voltages associated with the 3CN3-B result in production of X-radiation which may constitute a health hazard on prolonged exposure at close range unless the tube is adequately shielded. Equipment design must provide for this shielding.

Precautions must be exercised during the servicing of equipment employing the 3CN3-B to assure that the high voltage is adjusted to the recommended value and that any shielding components are replaced to their intended positions before the equipment is operated.

SHOCK HAZARD

The high voltages at which the 3CN3-B is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and for the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 3CN3-B in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

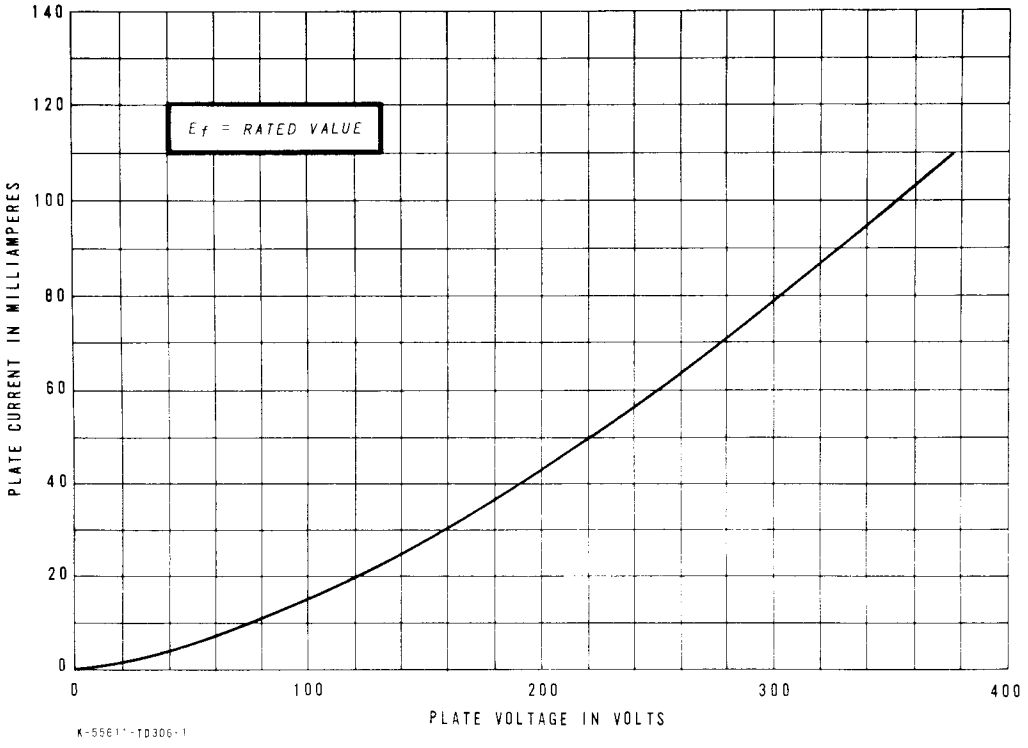
THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN.

NOTES

* The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

‡ Heater current of a bogey tube at Ef = 3.15 volts.

§ Without external shield.



\# Socket terminals 4 and 6 may be used as tie points for components at or near heater potential.

¶ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

PLANAR TRIODE

DESCRIPTION AND RATING

FOR GROUNDED-GRID OSCILLATOR, AMPLIFIER, AND FREQUENCY MULTIPLIER SERVICE

Metal and Ceramic — Pulse Rated
High Transconductance — Shock Resistant
100 Watts Plate Dissipation

The 3CX100A5 is a metal-and-ceramic, high-mu triode designed for use as a grounded-grid CW oscillator, amplifier, or frequency multiplier at frequencies as high as 2500 megacycles. In addition, it may be used as a plate-pulsed oscillator or amplifier at frequencies as high as 3000 megacycles.

Features of the 3CX100A5 include planar electrode construction, high plate dissipation capability, excellent electrode isolation, low radio-frequency losses, high transconductance, and low interelectrode capacitances.

* The equipment designer should design the equipment so that heater voltage is centered at some value within the range of 4.5 to 5.7 volts for CW operation, or 5.7 to 6.0 volts for pulse operation. Heater voltage variations about the center value should be kept as small as practical and should not, in any case, exceed ±5%. The optimum center value of heater voltage depends on the cathode current and on other parameters of circuit design and operation. For specific recommendations, contact your General Electric tube sales representative.

† Heater current of a bogey tube at Ef = 6.0 volts.

‡ Measured in a special shielded socket.

§ Modulation essentially negative may be used if the positive peak of the audio-frequency envelope does not exceed 115% of the carrier conditions.

¶ For modulation factors less than 1.0, a higher d-c plate voltage may be used if the sum of the peak positive audio voltage and the d-c plate voltage does not exceed 1200 volts.

⁂ Applications with a duty factor greater than 0.0025 should be referred to your General Electric tube sales representative for recommendations.

△ In any 5000-microsecond interval.

** The regulation and/or series plate-supply impedance must be such as to limit the peak current, with the tube considered a short circuit, to a maximum of 30 amperes.

†† The maximum instantaneous value should be within the range of +250 to −750 volts.

§§ Adjusted for Ib = 70 milliamperes.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

Diode

3DA3

FOR TV HIGH-VOLTAGE RECTIFIER APPLICATIONS

- COLOR TV TYPE
- 30000 VOLTS DC
- 2.2 MILLIAMPERES DC
- DIFFUSION BONDED CATHODE
- NEW RAPID WARM-UP HEATER-CATHODE DESIGN
- X-RADIATION RATING

The 3DA3 is a heater-cathode type diode designed for use in color television receivers as the high-voltage rectifier to supply power to the anode of the picture tube. Features of the tube include fast operational warm-up, a diffusion bonded cathode coating to minimize reverse emission failures, and X-radiation controls.

A unique design feature of the 3DA3 is a new heater-cathode system which enables a more rapid heat transfer from the heater to the cathode with low thermal inertia. Aiding in this accomplishment is the use of a thinner, high-strength, bi-metal cathode sleeve and the development of associated process techniques which expedite thermal conductivity without impairing the inherent reliability of the tube.

The diffusion bonded cathode coating practically eliminates one of the major failure mechanisms in high-voltage rectifiers, which is back-emission from the anode due to emissive particles being pulled from the cathode by the very high electrostatic field.

The 3DA3 features built-in X-radiation shielding and additional design and specification controls for the reduction of X-radiation output.

FLYBACK RECTIFIER SERVICE△ — DESIGN-MAXIMUM VALUES UNLESS OTHERWISE STATED

Peak Inverse Voltage		
DC Component (Absolute-Maximum Value)	30000	Volts
Total DC and Peak (Absolute-Maximum Value)	38000	Volts
Steady-State Peak Plate Current	110	Milliamperes
DC Output Current	2.2	Milliamperes
Heater Voltage, AC or DC (Absolute-Maximum Value)¢	3.65	Volts
Heater Voltage, AC or DC (Absolute-Minimum Value)	2.65	Volts

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

AVERAGE CHARACTERISTICS

Ib = 7.0 Milliamperes	60	Volts

X-RADIATION RATING△

X-radiation, maximum	25	mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 25 mR/hr at any time throughout their useful life, when operated within the maximum ratings, including heater voltage, specified on this data sheet.

This X-radiation maximum rating is based on data obtained with the use of the Victoreen 440 RF survey meter with a 3 3/8 inch aperture. X-radiation is measured with the face of the meter at a distance of 4 3/4 inches from the external surface of the tube. This rating information is not necessarily applicable when a different radiation measuring instrument or aperture is used.

Operation of the 3DA3 outside of the Absolute-Maximum Ratings indicated may damage the tube and/or result in either temporary or permanent changes in the X-radiation characteristics of the tube. Equipment design must be such that these Absolute-Maximum Rainges are not exceeded.

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein.

X-RADIATION CHARACTERISTICS

The 3DA3 will produce varying levels of X-radiation depending on operating conditions. Based on known attenuation factors of tube construction materials and accumulated sample test data taken initially and during life test, X-radiation output is not expected to exceed the maximum expected values indicated below for the different values of total DC and peak inverse voltage, with all other operating conditions remaining constant.

TOTAL DC AND PEAK INVERSE VOLTAGE	MAXIMUM EXPECTED X-RADIATION OUTPUT
38 KV (30 KV Maximum DC Component)	25.0 mR/hr
33 KV (27 KV Maximum DC Component)	3.0 mR/hr
30 KV (25 KV Maximum DC Component)	0.5 mR/hr

The above X-radiation characteristics are measured in accordance with JEDEC Publication No. 67, "Recommended Practice for Measurement of X-Radiation from Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73, "Recommended Practice for Quality Control of X-Radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

WARNING

X-RADIATION

The high voltages associated with the 3DA3 result in production of X-radiation which may constitute a health hazard on prolonged exposure at close range unless the tube is adequately shielded. Equipment design must provide for this shielding.

Precautions must be exercised during the servicing of equipment employing the 3DA3 to assure that the high voltage is adjusted to the recommended value and that any shielding components are replaced to their intended positions before the equipment is operated.

SHOCK HAZARD

The high voltages at which the 3DA3 is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and for the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 3DA3 in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN.

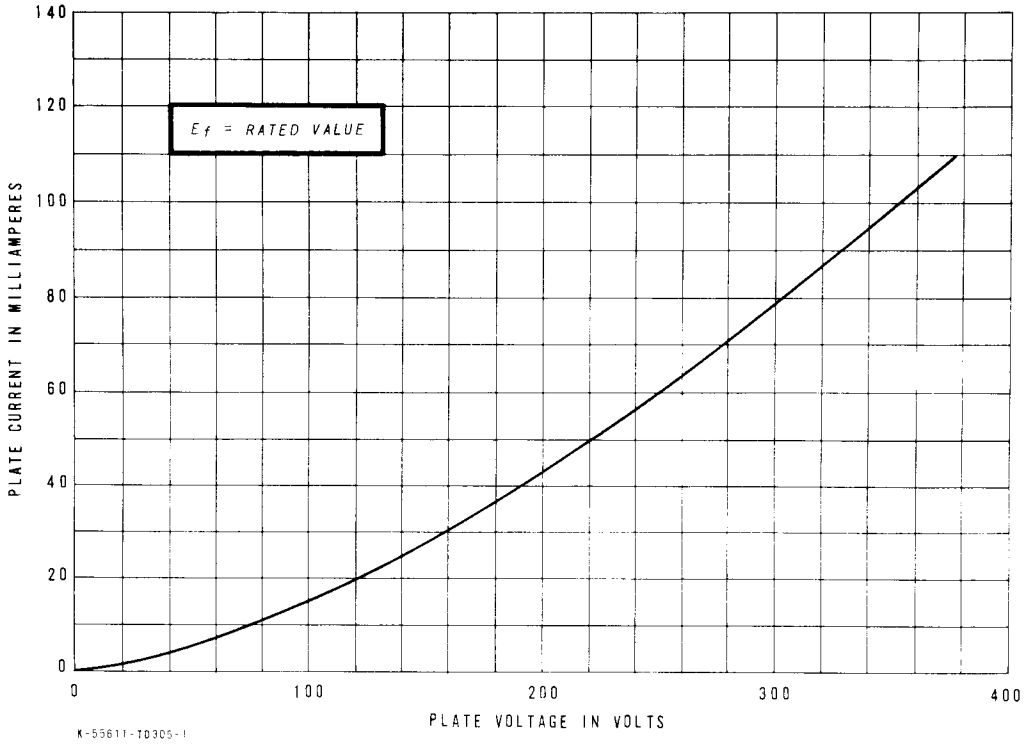
NOTES

* The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

‡ Heater current of a bogey tube at Ef = 3.15 volts.

§ The time required to reach 80 percent of rated d-c output voltage when used as a flyback rectifier.

¶ Without external shield.



Socket terminals 1 and 7 may be used as tie points for components at or near heater potential.

Δ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

¢ CAUTION - Operation of this tube for an extended period of time with the heater voltage above the absolute maximum rated value of 3.65 volts may result in the production of X-radiation in excess of the maximum rated limit of 25 mR/hr.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

Tube Voltage Drop		
Ib = 350 Milliamperes DC per Plate	25	Volts

To simplify the application of the maximum ratings to circuit design, the Design-Maximum ratings are presented in chart form as Rating Charts I, II, and III. Rating Chart I presents the maximum ratings for a-c plate-supply voltage and d-c output current. Rating Chart II provides a convenient method for checking conformance with the maximum steady-state peak-plate-current rating. Rating Chart III offers a convenient method for checking conformance with the maximum transient peak-plate-current rating. Rating Chart I applies to both capacitor-input and choke-input filters, while Rating Charts II and III apply to capacitor-input filters only.

Operating points should be so selected that the boundary limits of a-c plate-supply voltage and d-c output current on Rating Chart I, and maximum d-c output current per plate and rectification efficiency on Rating Chart II, are not exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, and environmental conditions. On Rating Chart I the boundary FAEDG defines the limits for capacitor-input filter operation, and the boundary FABCDG defines the limits for choke-input filter operation.

Rating Chart III shows the minimum value of plate-supply resistance (R_s) required to remain within the transient peak-plate-current rating. The value of R_s should be such that it lies to the left of the line on Rating Chart III at the highest probable value of line voltage.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

AVERAGE CHARACTERISTICS

Tube Voltage Drop, approximate		
Ib = 7.0 Milliamperes	70	Volts

X-RADIATION RATING⊕

X-radiation, maximum	25	mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 25 mR/hr at any time throughout their useful life, when operated within the maximum ratings, including heater voltage, specified on this data sheet.

This X-radiation maximum rating is based on the use of the Victoreen 440 RF/C survey meter as the standard instrument for X-radiation measurement. X-radiation is measured with the plastic spacer of the 440 RF/C survey meter at a distance of four (4) inches from the external surface of the tube under test. This rating information is not necessarily applicable when a different radiation measuring instrument is used.

Operation of the 3DH3 outside of the Absolute-Maximum Ratings indicated may damage the tube and/or result in either temporary or permanent changes in the X-radiation characteristics of the tube. Equipment design must be such that these Absolute-Maximum Ratings are not exceeded.

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein.

X-RADIATION CHARACTERISTICS

The 3DH3 will produce varying levels of X-radiation depending on operating conditions. Based on known attenuation factors of tube construction materials and accumulated sample test data taken initially and during life test, X-radiation output is not expected to exceed the maximum expected values indicated below for the different values of total DC and peak inverse voltage, with all other operating conditions remaining constant.

TOTAL DC AND PEAK INVERSE VOLTAGE	MAXIMUM EXPECTED X-RADIATION OUTPUT
38 KV (30 KV Maximum DC Component)	25.0 mR/hr
33 KV (27 KV Maximum DC Component)	3.0 mR/hr
30 KV (25 KV Maximum DC Component)	0.5 mR/hr

The above X-radiation characteristics are measured in accordance with JEDEC Publication No. 67A, "Recommended Practice for Measurement of X-radiation from Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73A, "Recommended Practice for Quality Control of X-radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

WARNING

X-RADIATION

The high voltages associated with the 3DH3 result in production of X-radiation which may constitute a health hazard on prolonged exposure at close range unless the tube is adequately shielded. Equipment design must provide for this shielding.

Precautions must be exercised during the servicing of equipment employing the 3DH3 to assure that the high voltage is adjusted to the recommended value and that any shielding components are replaced to their intended positions before the equipment is operated.

SHOCK HAZARD

The high voltages at which the 3DH3 is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and for the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 3DH3 in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN.

NOTES

★ The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

● Heater current of a bogey tube at Ef = 3.15 volts.

♦ Without external shield.

▲ Socket terminals 1, 2 and 7 may be used as tie points for components at or near heater potential.

⊕ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

§ **CAUTION** - Operation of this tube for an extended period of time with the heater voltage above the absolute maximum rated value of 3.65 volts may result in the production of X-radiation in excess of the maximum rated limit of 25 mR/hr.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

3DJ3

FOR TV HIGH-VOLTAGE RECTIFIER APPLICATIONS

- COLOR TV TYPE
- 30000 VOLTS DC
- 2.0 MILLIAMPERES DC
- DIFFUSION BONDED CATHODE
- X-RADIATION RATING

The 3DJ3 is a heater-cathode type diode designed for use in color television receivers as the high-voltage rectifier to supply power to the anode of the picture tube. Features of the tube include a diffusion bonded cathode coating to minimize reverse emission failures, and X-radiation controls.

The diffusion bonded cathode coating practically eliminates one of the major failure mechanisms in high-voltage rectifiers, which is back-emission from the anode due to emissive particles being pulled from the cathode by the very high electrostatic field.

The 3DJ3 features built-in X-radiation shielding and additional design and specification controls for the reduction of X-radiation output.

Ib = 7.0 Milliamperes ..... 70 Volts

X-RADIATION RATING §

MAXIMUM RATED OPERATING CONDITIONS

Total DC and Peak Inverse Voltage	Maximum X-Radiation Output
⊕ 38 KV	0.5 mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 0.5 mR/hr at any time throughout their useful life, when operated within the maximum ratings, including heater voltage, specified on this data sheet.

This X-radiation maximum rating is based on the the use of the Victoreen 440 RF/C survey meter as the standard instrument for X-radiation measurement. X-radiation is measured with the plastic spacer of the 440 RF/C survey meter at a distance of four (4) inches from the external surface of the tube under test. This rating information is not necessarily applicable when a different radiation measuring instrument is used.

Operation at voltages outside of the Absolute-Maximum Ratings will cause permanent damage to the tube resulting in short life and/or catastrophic failure. Any tube known to have operated above 38 KV peak inverse voltage and/or 3.65 V heater voltage should be replaced with the latest version of the same tube type.

The X-radiation characteristics are measured in accordance with JEDEC Publication No. 67A, "Recommended Practice for Measurement of X-Radiation from Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73A, " Recommended Practice for Quality Control of X-Radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein, except as noted under "X-Radiation Characteristics."

X-RADIATION CHARACTERISTICS

EQUIPMENT MISADJUSTMENT AND/OR CIRCUIT FAILURE MODE OPERATION

The 3DR3 is designed to limit X-radiation to 0.5 mR/hr provided its protective shield has not been removed or damaged. Based on known attenuation factors of tube construction materials and accumulated sample test data taken initially and during life test, X-radiation output is not expected to exceed the indicated value under equipment misadjustment and/or circuit failure mode operations of plate and heater voltage listed below.

Total DC and Peak Inverse Voltage	Maximum Heater Voltage	Maximum Expected X-Radiation Output
⊕41 KV	⊕4.8 V	0.5 mR/hr

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated with total DC and peak inverse voltage above 41 KV.

Operation at voltages outside of the Absolute-Maximum Ratings will cause permanent damage to the tube resulting in short life and/or catastrophic failure. Any tube known to have operated above 38 KV peak inverse voltage and/or 3.65 V heater voltage should be replaced with the latest version of the same tube type.

WARNING

X-RADIATION

X-radiation in excess of 0.5 mR/hr may constitute a health hazard on prolonged exposure at close range. Therefore, equipment design must provide for adequate shielding.

Operation of the 3DR3 with total DC and peak inverse voltage greater than 41 KV may result in radiation in excess of the "Maximum Expected X-Radiation Output" listed under "X-Radiation Characteristics."

Precautions must be exercised during servicing of equipment employing the 3DR3 to assure that the high voltage is adjusted to the recommended value and that the tube's protective shield is not damaged. **IF THE PROTECTIVE SHIELD IS REMOVED OR DAMAGED IN ANY WAY, THE 3DR3 MUST BE REPLACED WITH THE LATEST VERSION OF THE SAME TUBE TYPE.**

SHOCK HAZARD

The high voltages at which the 3DR3 is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and in the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 3DR3 in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

ARC TEST FOR HIGH VOLTAGE

The practice of checking for high voltage by drawing an arc from the top cap can permanently damage the protective shield which will necessitate replacing the tube.

THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN.

NOTES

★ The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

● Heater current of a bogey tube at Ef = 3.15 volts.

▲ Without external shield.

♦ Socket terminals 4 and 7 may be used as tie points for components at or near heater potential.

§ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

℔ **CAUTION** - Operation at voltages outside of the Absolute-Maximum Ratings will cause permanent damage to the tube resulting in short life and/or catastrophic failure. Any tube known to have operated above 38 KV peak inverse voltage and/or 3.65 V heater voltage should be replaced with the latest version of the same tube type.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

Total DC and Peak Inverse Voltage	Maximum Heater Voltage	Maximum Expected X-Radiation Output
⊕41 KV	⊕4.8 V	0.5 mR/hr

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated with total DC and peak inverse voltage above 41 KV.

Operation at voltages outside of the Absolute-Maximum Ratings will cause permanent damage to the tube resulting in short life and/or catastrophic failure. Any tube known to have operated above 38 KV peak inverse voltage and/or 3.65 V heater voltage should be replaced with the latest version of the same tube type.

WARNING

X-RADIATION

X-radiation in excess of 0.5 mR/hr may constitute a health hazard on prolonged exposure at close range. Therefore, equipment design must provide for adequate shielding.

Operation of the 3DS3 with total DC and peak inverse voltage greater than 41 KV may result in radiation in excess of the "Maximum Expected X-radiation Output" listed under "X-Radiation Characteristics."

Precautions must be exercised during servicing of equipment employing the 3DS3 to assure that the high voltage is adjusted to the recommended value and that the tube's protective shield is not damaged. **IF THE PROTECTIVE SHIELD IS REMOVED OR DAMAGED IN ANY WAY, THE 3DS3 MUST BE REPLACED WITH THE LATEST VERSION OF THE SAME TUBE TYPE.**

SHOCK HAZARD

The high voltages at which the 3DS3 is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and in the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 3DS3 in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

ARC TEST FOR HIGH VOLTAGE

The practice of checking for high voltage by drawing an arc from the top cap can permanently damage the protective shield which will necessitate replacing the tube.

THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN.

NOTES

* The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

● Heater current of a bogey tube at Ef = 3.15 volts.

▲ Without external shield.

♦ Socket terminals 4 and 7 may be used as tie points for components at or near heater potential.

§ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

⊕ **CAUTION** - Operation at voltages outside of the Absolute-Maximum Ratings will cause permanent damage to the tube resulting in short life and/or catastrophic failure. Any tube known to have operated above 38 KV peak inverse voltage and/or 3.65 V heater voltage should be replaced with the latest version of the same tube type.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

Electronic TUBE

3V4
Description and Rating
PENTODE

The 3V4 is a miniature power-amplifier pentode designed for use in the power output stage of compact, battery-operated equipment. It is particularly useful in three-way portable receivers which employ 90-volt batteries. The filament is center-tapped to permit operation from either a 2.8-volt or 1.4-volt filament supply voltage.

GENERAL

Cathode - Coated Filament

	Series*	Parallel*	
Filament Voltage, D-C	2.8	1.4	Volts
Filament Current	0.05	0.1	Ampere

Envelope - T-5½, Glass
Base - E7-1, Miniature Button 7-Pin
Mounting Position - Any

Direct Interelectrode Capacitances +

Grid-Number 1 to Plate	0.2	μμf
Input	5.5	μμf
Output	3.8	μμf

Transconductance	2000	1975	2150	Micromhos
Zero-Signal Plate Current	7.7	6.9	9.5	Milliamperes
Zero-Signal Screen Current	1.7	1.5	2.1	Milliamperes
Load Resistance	10000	10000	10000	Ohms
Total Harmonic Distortion, approximate	7	10	7	Percent
Maximum-Signal Power Output	0.24	0.25	0.27	Watt

* *For series-filament operation the positive filament voltage is connected to pin 7, and the negative filament voltage is connected to pin 1. For parallel-filament operation the positive filament voltage is connected to pins 1 and 7 tied together, and the negative filament voltage is connected to pin 5. In each case, all voltages are referred to the negative terminal of the filament.*

§ *Value is for each filament section. With series-filament operation, a resistor must be connected across the negative filament section to bypass any cathode current in excess of the rated maximum. When other tubes in a series-filament arrangement contribute to the filament current of the 3V4, an additional shunting resistor may be required across the entire filament.*

\+ *Without external shield.*

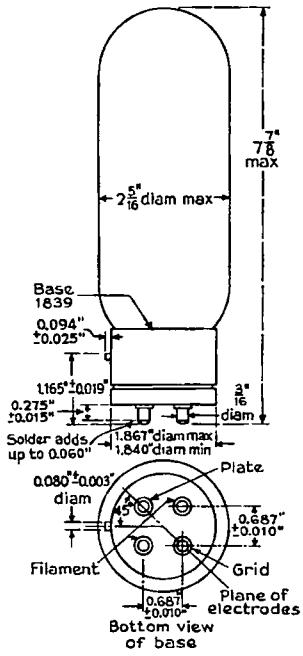
* Averaged over any audio frequency cycle.
** At crest of audio-frequency cycle.
***Modulation, essentially negative, may be used if the positive peak of the audio-frequency envelope does not exceed 115 per cent of the carrier conditions.

The normal value of grid leak, when the tube is used as an oscillator or r-f power amplifier (Class C), is in the neighborhood of 5000 ohms, although this may be replaced by a suitable fixed bias. If self-bias is used the cathode resistor should be approximately 1000 ohms.

The 4C21 can be operated at frequencies as high as 15 megacycles. It may be operated at higher frequencies provided the maximum values of plate voltage and power input are reduced as the frequency is raised (other maximum ratings are the same as shown above).

The tabulation below shows the highest percentage of maximum plate voltage and power input that should be used up to 80 megacycles for the various classes of service.



Special attention should be given to adequate ventilation of the bulb at these frequencies.

FREQUENCY	15	30	80	megacycles

PERCENTAGE OF MAXIMUM RATED PLATE VOLTAGE AND PLATE INPUT

Class B	100	88	70	per cent
Class C	100	80	50	per cent

The resonant frequency of the grid-plate circuit is approximately 100 megacycles.

DESCRIPTION AND RATING

4CB6

4CB6 Pentode. Except for heater ratings and heater-cathode ratings, the 4CB6 is identical to the 6CB6-A.

GENERAL

ELECTRICAL

Heater Characteristics and Ratings		
Heater Voltage, AC or DC¶	4.2	Volts
Heater Current†	0.45 ± 0.03	Amperes
Heater Warm-up Time‡	11	Seconds

MAXIMUM RATINGS

DESIGN-MAXIMUM VALUES

Heater-Cathode Voltage		
Heater Positive with Respect to Cathode		
DC Component	100	Volts
Total DC and Peak	200	Volts
Heater Negative with Respect to Cathode		
DC Component	200	Volts
Total DC and Peak	300	Volts

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

GENERAL ELECTRIC

from JEDEC release #4449, Oct. 7, 1963

MAXIMUM RATINGS (Cont'd)

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

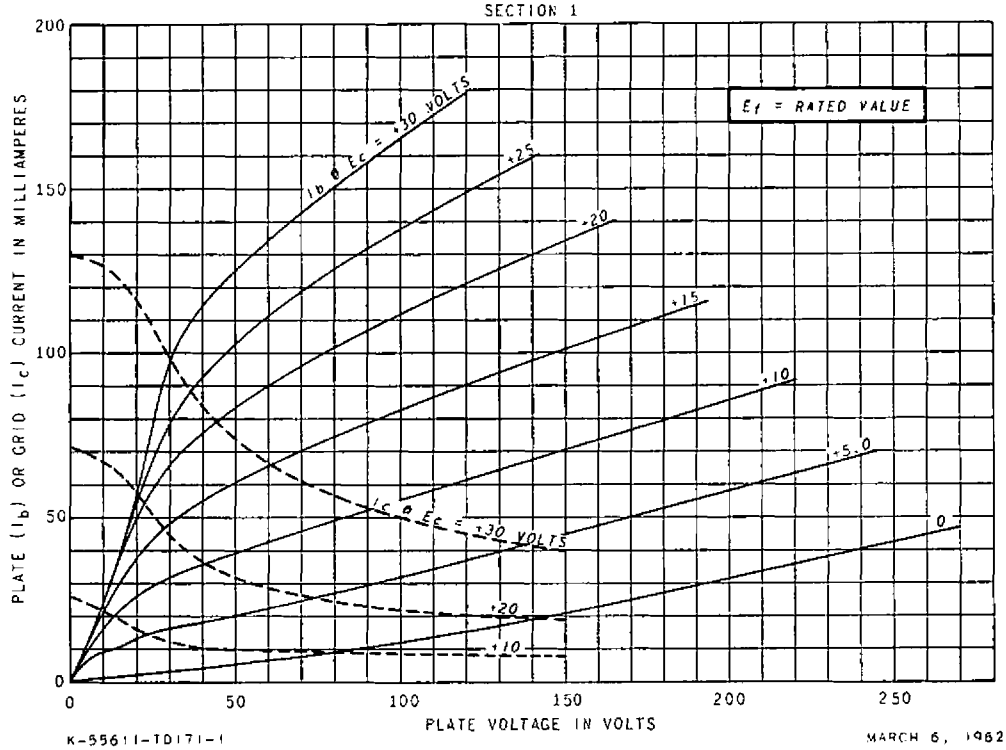
CHARACTERISTICS AND TYPICAL OPERATION

AVERAGE CHARACTERISTICS

	Section 1	Section 2	
Plate Voltage	250	250	Volts
Grid Voltage	-8.5	-2.0	Volts
Amplification Factor	17	100	
Plate Resistance, approximate	7700	62500	Ohms
Transconductance	2200	1600	Micromhos
Plate Current	10.5	1.2	Milliamperes
Grid Voltage, approximate Ib = 10 Microamperes	-24	---	Volts

NOTES

* Heater voltage for a bogey tube at If = 0.6 amperes.



‡ The equipment designer should design the equipment so that heater current is centered at the specified bogey value, with heater supply variations restricted to maintain heater current within the sepcified tolerance.

§ The time required for the voltage across the heater to reach 80 percent of the bogey value after applying 4 times the bogey heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the bogey heater voltage divided by the bogey heater current.

To simplify the application of the maximum ratings to circuit design, the Design-Maximum ratings are presented in chart form as Rating Charts I, II, and III. Rating Chart I presents the maximum ratings for a-c plate supply voltage and d-c output current. Rating Chart II provides a convenient method for checking conformance with the maximum steady-state peak-plate-current rating. Rating Chart III offers a convenient method for checking conformance with the maximum transient peak-plate-current rating. Rating Chart I applies to both capacitor-input and choke-input filters, while Rating Charts II and III apply to capacitor-input filters only.

Operating points should be so selected that the boundary limits of a-c plate supply voltage and d-c output current on Rating Chart I, and maximum d-c output current per plate and rectification efficiency on Rating Chart II, are not exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, and environmental conditions. On Rating Chart I the boundary FAEDG defines the limits for capacitor-input filter operation, and the boundary FABCDG defines the limits for choke-input filter operation.

Rating Chart III shows the minimum value of plate supply resistance (R_s) required to remain within the transient peak-plate-current rating. The value of R_s should be such that it lies to the left of the line on Rating Chart III at the highest probable value of line voltage.

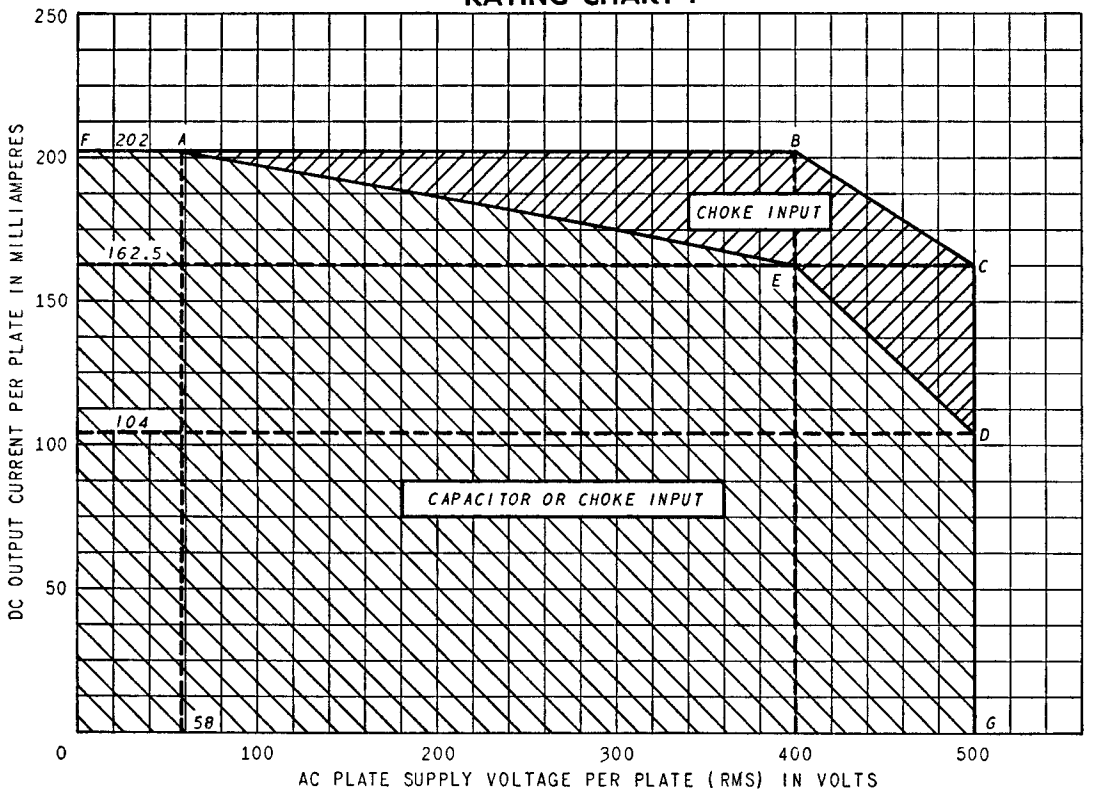
PHYSICAL DIMENSIONS



* Horizontal operation is permitted if pins 2 and 4 are in a vertical plane.

† For use with sinusoidal supply voltages within the frequency range of 25 to 1000 cycles per second.

‡ To simplify the application of the maximum ratings to circuit design, the electrical design-center maximum ratings are also presented in chart form as Rating Charts I, II, and III. Rating Chart I presents the maximum ratings for a-c plate supply voltage and d-c output current. Rating Chart II provides a convenient method for checking conformance with the maximum steady-state peak-plate-current rating. Rating Chart III offers a convenient method for checking conformance with the maximum transient peak-plate-current rating.
With a capacitor-input filter, the conditions of each of Rating Charts I, II, and III must be satisfied in order to obtain performance within all of the appropriate electrical maximum ratings. With a choke-input filter, operation within the indicated boundary of Rating Chart I will assure performance within all of the appropriate electrical maximum ratings.

§ The maximum ratings for a-c plate supply voltage and d-c output current are interrelated and are also dependent on whether a choke- or capacitor-input filter is employed. This relationship is shown in Rating Chart I. With a capacitor-input filter, the operating point of d-c output current and a-c supply voltage must fall within the curve FAEDG. With a choke-input filter, the operating point must fall within the curve FABCDG.

Electronic TUBES

5DH8

TRIODE-PENTODE

DESCRIPTION AND RATING

The 5DH8 is a miniature tube which contains a sharp-cutoff pentode and a high-mu triode in one envelope. The pentode section is intended for use as a video intermediate-frequency amplifier or as an audio intermediate-frequency amplifier. Provided the cathode is grounded, the triode section may be used as vertical oscillator, sync amplifier, sync separator, or sync clipper.

The 5DH8 features an internal connection between the pentode suppressor and the triode cathode, to enable the grounding of the suppressor when a cathode-bias resistor is employed for the pentode section. The tube also has a controlled heater warm-up characteristic which makes it especially suited for use in television receivers that employ 600-milliampere, series-connected heaters.

Design-Maximum Ratings are the limiting values expressed with respect to bogie tubes at which satisfactory tube life can be expected to occur for the types of service for which the tube is rated. Therefore, the equipment designer must establish the circuit design so that initially and throughout equipment life no design-maximum value is exceeded with a bogie tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, and environmental conditions.

PRODUCT INFORMATION

5KZ8

Triode-Pentode

The 5KZ8 is a miniature tube containing a sharp-cutoff pentode and a medium-mu triode. It is intended primarily for service as a combined triode oscillator and pentode mixer in VHF television tuners.

Except for heater characteristics, the 5KZ8 is identical to the 6KZ8 and the 9KZ8.

DESCRIPTION AND RATING

CATHODE-RAY TUBE 5QP4

5-INCH ROUND, GLASS — DEFLECTION - MAGNETIC

FOCUS - MAGNETIC — FACEPLATE - CLEAR, METAL BACKED

The 5QP4 is a magnetic-focus and magnetic-deflection direct-view cathode-ray tube for industrial applications. A feature of this tube is a reflective metal-backed screen which reduces undesirable screen charging and increases high-light brightness.

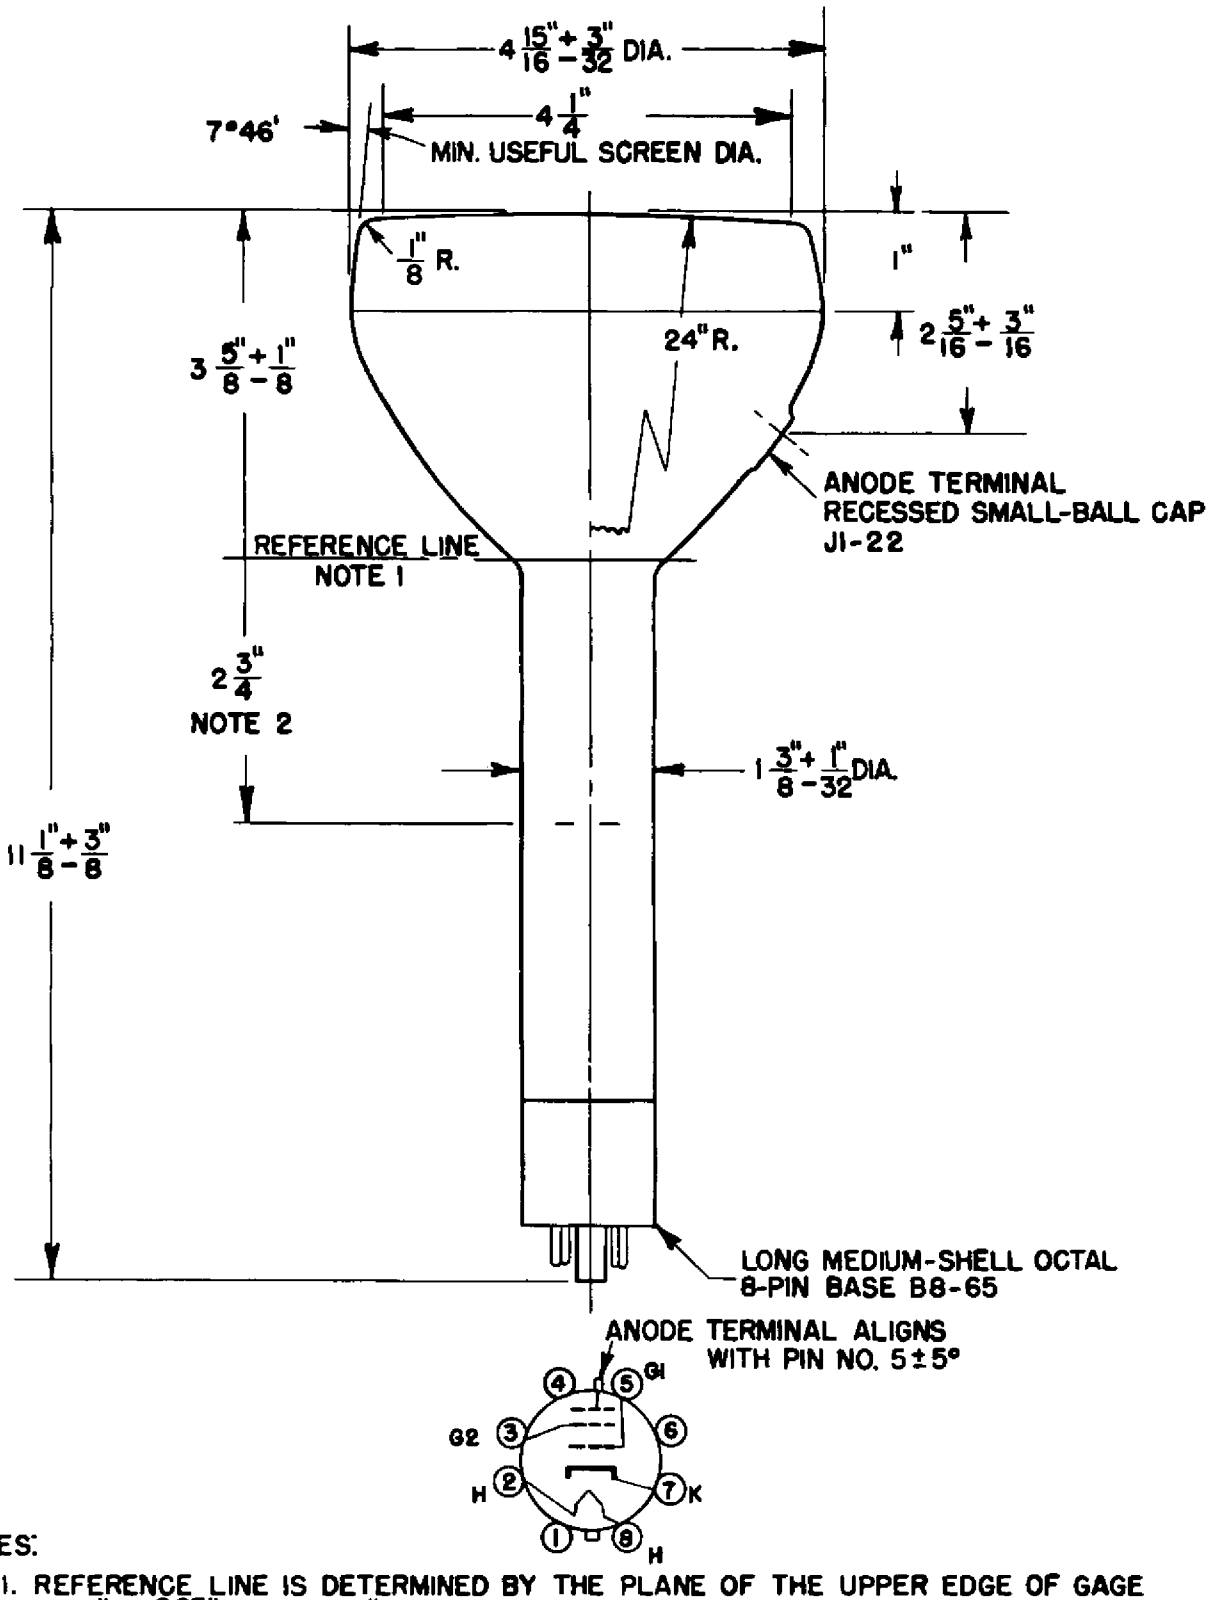
MAXIMUM CIRCUIT VALUES

Grid-No. 1 Circuit Resistance	1.5 Max	Megohms



* At or near this rating, the effective resistance of the anode supply should be adequate to limit the anode input power to 6 watts.

† Cathode should be returned to one side or to the midtap of the heater transformer winding.

‡ For visual extinction of undeflected focused spot.

§ For RTMA focusing coil No. 106 or equivalent, with the combined grid-No. 1 bias voltage and video-signal voltage adjusted to produce a high-light brightness of 20 foot-lamberts on a 2 7/8- by 3 7/8-inch picture area and with the distance from the reference line to center of air gap equal to 2 3/4 inches.

◊ Brilliance and definition decrease with decreasing anode voltage. In general the anode voltage should not be less than 5000 volts.

NOTES:

1. REFERENCE LINE IS DETERMINED BY THE PLANE OF THE UPPER EDGE OF GAGE 1.430" $^{+.003"}_{-.000"}$ ID AND 2" LONG WHEN THE GAGE IS RESTING ON THE BULB.
2. RECOMMENDED POSITION FOR CENTER OF FOCUSING FIELD.

HIGH-RESOLUTION GUN
ALUMINIZED SCREEN

DESCRIPTION AND RATING

The 5QP4-A is a magnetic-focus and -deflection direct-view cathode-ray tube for use as a view-finder for television cameras. It has a high-resolution gun which affords an exceptionally narrow trace on the fluorescent screen. The screen is aluminized to increase light output, reduce undesirable screen charging, and prevent ion-spot blemish.

TELEVISION PICTURE TUBE

DESCRIPTION

The 5TP4 is a five-inch electrostatic-focus and magnetic-deflection projection picture tube for television applications. It is designed for use with a reflective optical system. Features of this tube are a reflective metal-backed screen which gives improved brightness, picture contrast and detail, and an external conductive coating on the neck which acts as a corona shield when grounded.

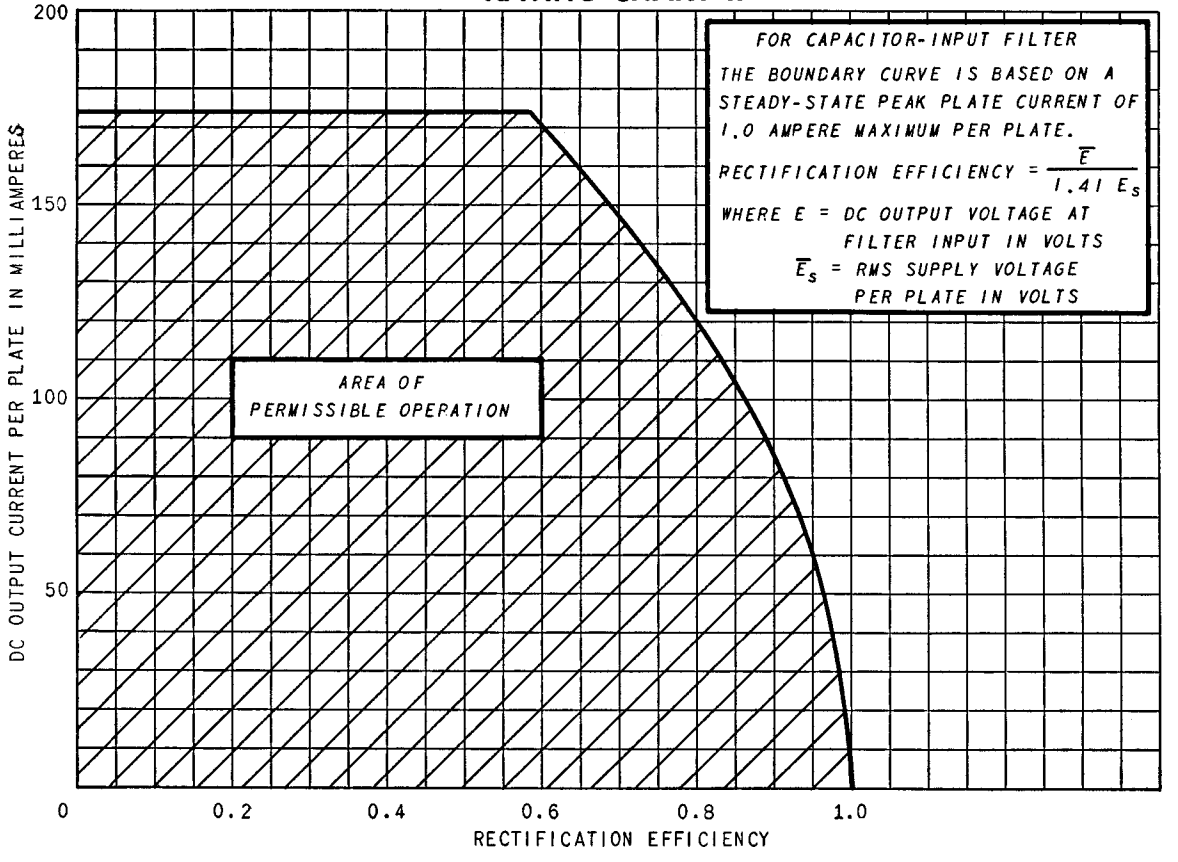
* Horizontal operation is permitted if pins 1 and 4 are in a vertical plane.

† To simplify the application of the maximum ratings to circuit design, the electrical design-center maximum ratings are also presented in chart form as Rating Charts I, II, and III. Rating Chart I presents the maximum ratings for a-c plate supply voltage and d-c output current. Rating Chart II provides a convenient method for checking conformance with the maximum steady-state peak-plate-current rating. Rating Chart III offers a convenient method for checking conformance with the maximum transient peak-plate-current rating. With a capacitor-input filter, the conditions of each of Rating Charts I, II, and III must be satisfied; with a choke-input filter, operation must be within the indicated boundary of Rating Chart I.



‡ The maximum ratings for a-c plate supply voltage and d-c output current are interrelated and are also dependent on whether a choke- or capacitor-input filter is employed. This relationship is shown in Rating Chart I. With a capactor-input filter, the operating point of d-c output current and a-c supply voltage must fall within the curve FAEDG. With a choke-input filter, the operating point must fall within the curve FABCDG.

NOTE: The indicated values of a-c plate-supply voltage shown throughout the data are measured without load.

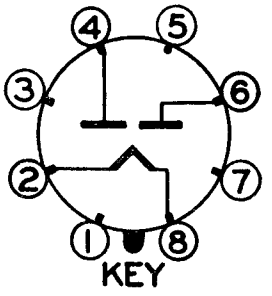
Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey tube of a specified type as defined by its published data, and should not be exceeded under the worst probable conditions.



These values are chosen by the tube manufacturer to provide acceptable serviceability of the tube, taking responsibility for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, variation in characteristics of all other tubes in the equipment, equipment control adjustment, load variation, signal variation, and environmental conditions.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

* Horizontal operation is permitted if pins 2 and 4 are in a vertical plane.

To simplify the application of the maximum ratings to circuit design, the Design-Maximum ratings are presented in chart form as Rating Charts I, II, and III. Rating Chart I presents the maximum ratings for a-c plate supply voltage and d-c output current. Rating Chart II provides a convenient method for checking conformance with the maximum steady-state peak-plate-current rating. Rating Chart III offers a convenient method for checking conformance with the maximum transient peak-plate-current rating. Rating Chart I applies to both capacitor-input and choke-input filters, while Rating Charts II and III apply to capacitor-input filters only.

Operating points should be so selected that the boundary limits of a-c plate supply voltage and d-c output current on Rating Chart I, and maximum d-c output current per plate and rectification efficiency on Rating Chart II, are not exceeded with a bogey tube under the worst probable conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, and environmental conditions. On Rating Chart I the boundary FAEDG defines the limits for capacitor-input filter operation, and the boundary FABCDG defines the limits for choke-input filter operation.

Rating Chart III shows the minimum value of plate-supply resistance (R_s) required to remain within the transient peak-plate-current rating. The value of R_s should be such that it lies to the left of the line on Rating Chart III at the highest probable value of line voltage.

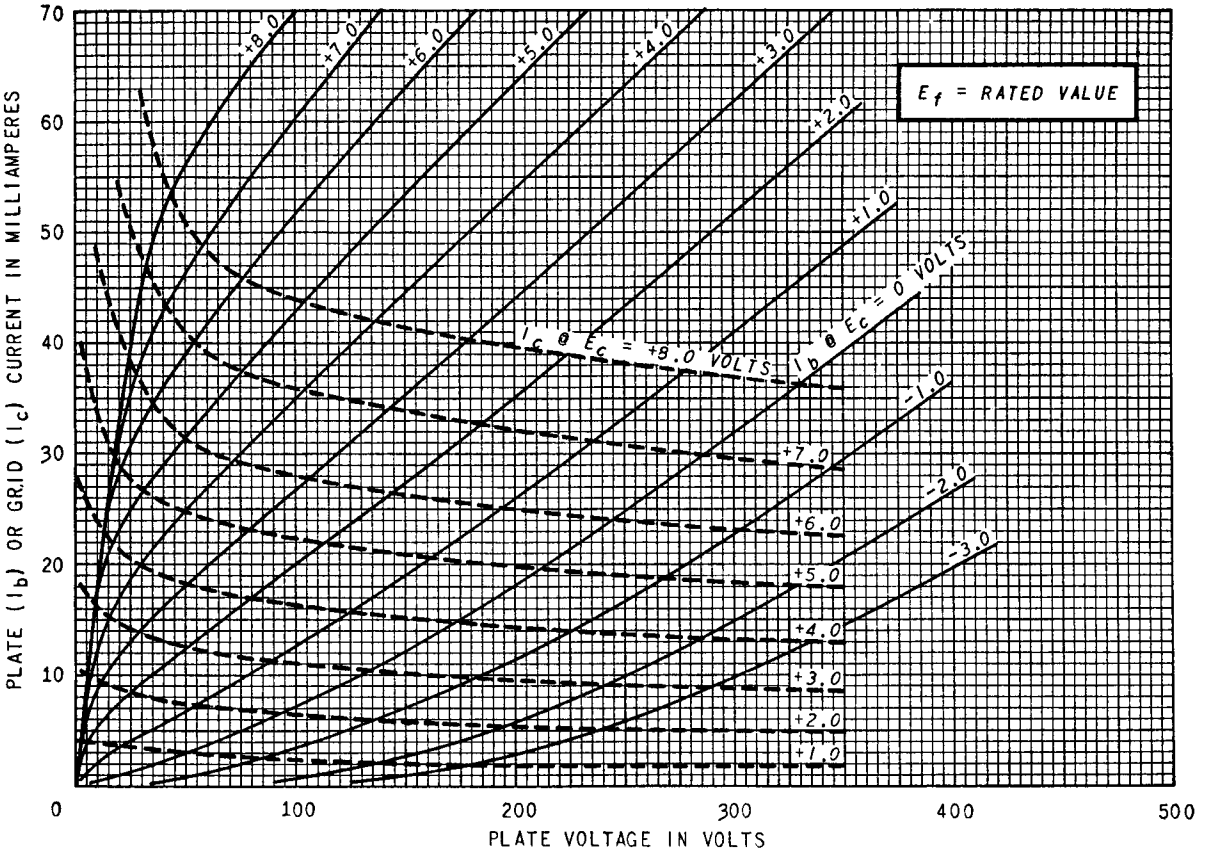
Design-Center ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under normal conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube in average applications, making allowance for normal changes in operating conditions due to rated supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.



The equipment manufacturer should design so that initially no design-center value for the intended service is exceeded with a bogey tube under normal operating conditions at the stated normal supply voltage.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

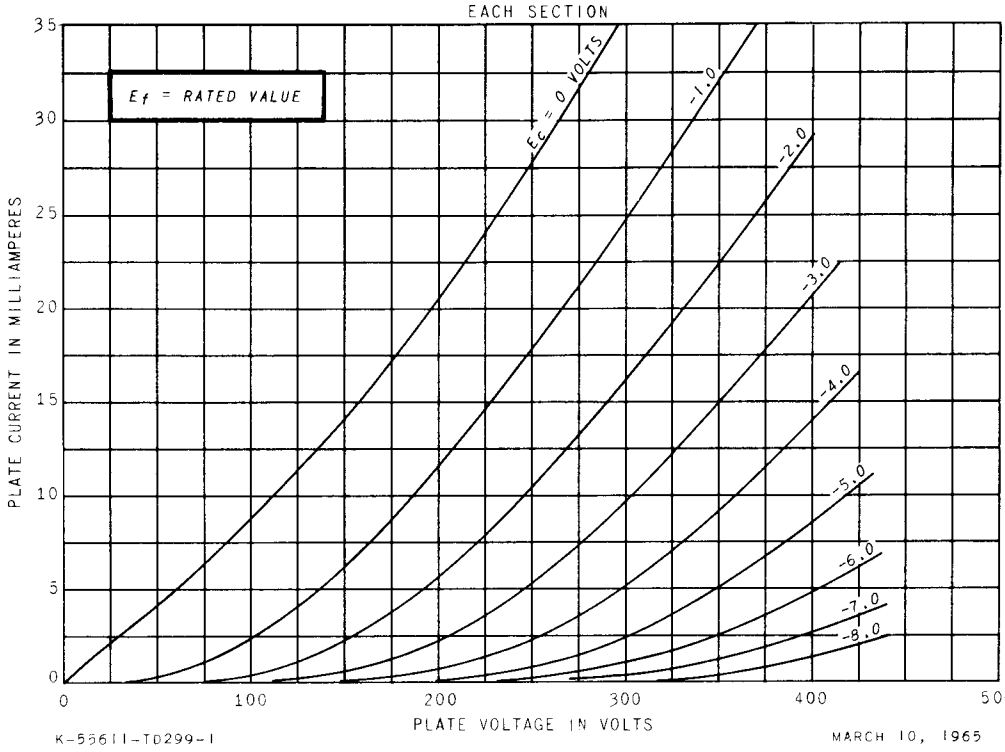
* Operated with the heater in series with the heaters of other tubes having the same bogey heater current.

‡ Operated with the heater in parallel with the heaters of other tubes having the same bogey heater voltage.

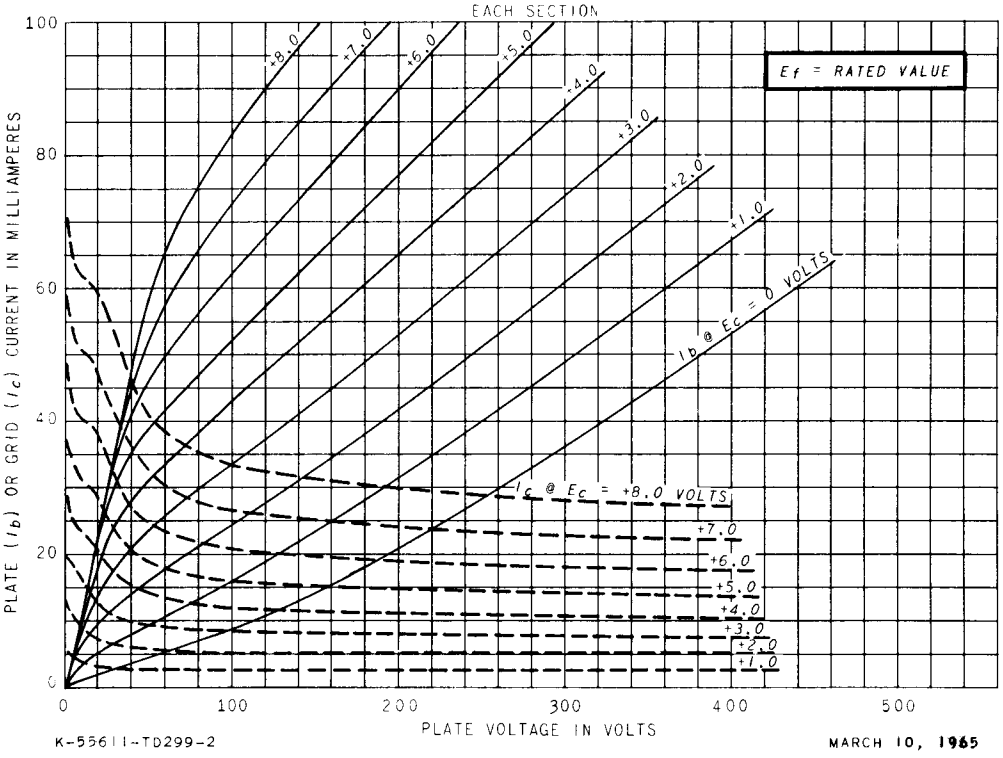
§ For parallel heater operation, the equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

¶ For series heater operation, the equipment designer should design the equipment so that heater current is centered at the specified bogey value, with heater supply variations restricted to maintain heater current within the specified tolerance.



Δ Heater current of a bogey tube at Ef = 6.3 volts.

\# The time required for the voltage across the heater to reach 80 percent of the bogey value after applying 4 times the bogey heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the bogey heater voltage divided by the bogey heater current.



** Without external shield.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

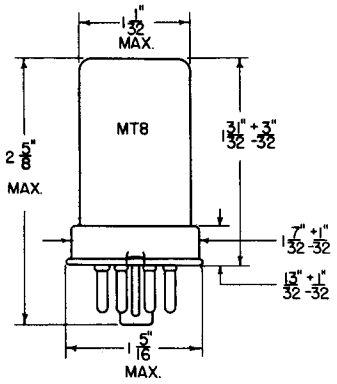
6AC7

Description and Rating



RADIO-FREQUENCY AMPLIFIER PENTODE

GENERAL DESCRIPTION

Principal Application: The 6AC7 is a sharp-cutoff high-transconductance pentode intended for service as a wide-band video or radio-frequency amplifier. It is also suitable for use as a mixer or oscillator at low frequencies, but it is not recommended for low-level audio-frequency applications unless the heater voltage is obtained from a d-c source. The use of cathode-bias is recommended.

Cathode	Coated Unipotential
Heater Voltage (A-C or D-C)	6.3 Volts
Heater Current	0.45 Ampere
Envelope	MT-8, Metal Shell
Base	B8-21, Small Wafer Octal 8-Pin
Mounting Position	Any
Direct Interelectrode Capacitances: #	
Grid 1 to Plate (Max)	0.015 μμf
Input	11 μμf
Output	5 μμf

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

MAXIMUM RATINGS (CONT'D)

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

CHARACTERISTICS AND TYPICAL OPERATION

AVERAGE CHARACTERISTICS, EACH SECTION

Plate Voltage	125	Volts
Grid Voltage	−1.0	Volts
Amplification Factor	66	
Plate Resistance, approximate	8500	Ohms

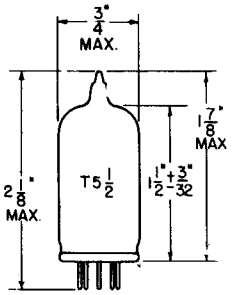
Description and Rating

RADIO-FREQUENCY AMPLIFIER PENTODE

GENERAL DESCRIPTION



Principal Application: The 6AG5 is a miniature sharp-cutoff pentode designed for use as an intermediate-frequency amplifier or radio-frequency amplifier up to frequencies of approximately 400 megacycles. The tube features high transconductance and low input and output capacitances. The use of two cathode leads facilitates isolation of the input and output circuits and thus minimizes degeneration.

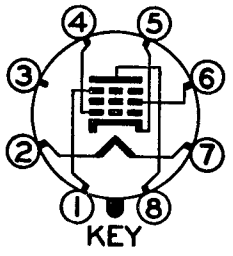
Design-Center ratings are limiting values of operating and environmental conditions applicable to a bogey tube of a specified type as defined by its published data, and should not be exceeded under normal conditions.

These values are chosen by the tube manufacturer to provide acceptable serviceability of the tube in average applications, taking responsibility for normal changes in operating conditions due to rated supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all tubes.



The equipment manufacturer should design so that initially no design-center value for the intended service is exceeded with a bogey tube in equipment operating at the stated normal supply-voltage.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

6AH4-GT
Description and Rating

TRIODE

FOR TV VERTICAL-DEFLECTION AMPLIFIER APPLICATIONS

The 6AH4-GT is a low-mu triode designed primarily for use as a vertical deflection amplifier in television receivers. The tube features high plate current at low plate voltages and is capable of withstanding the high pulse voltages normally encountered in this application. The 6AH4-GT, when operated from relatively low plate-supply voltages, is capable of deflecting fully large-deflection-angle picture tubes.

With Cathode Bias	0.25	---	Megohms

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

CHARACTERISTICS AND TYPICAL OPERATION

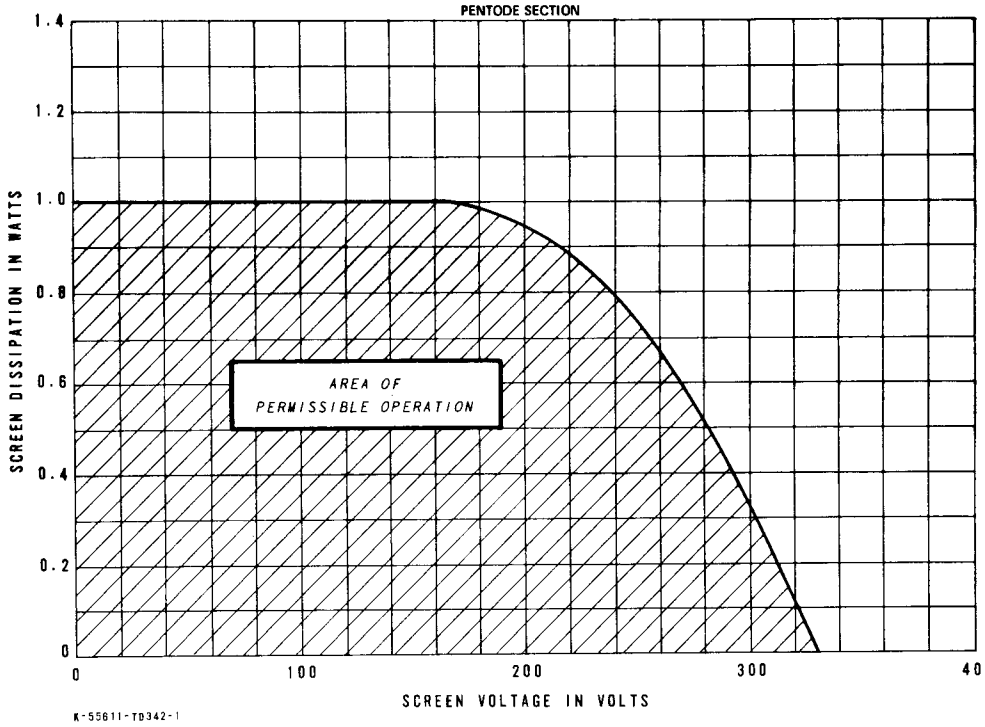
Screen Current	32	6.0	---	Milliamperes
Grid-Number 1 Voltage, approximate				
Ib = 100 Microamperes	---	-7.2	-18	Volts

NOTES

★ The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

● Heater current of a bogey tube at Ef = 6.3 volts.



♦ Without external shield.

▲ Control grid to cathode spacing of the pentode section of this tube is of such low order of magnitude as to preclude the use of voltage between these elements of more than 50 volts dc or peak ac in commercial tube checkers and shorts-indicating devices, particularly where mechanical excitation of the tube is employed.

§ Applied for short interval (two seconds maximum) so as not to damage tube.

Compactron Dissimilar-Double-Triode Pentode

6AK9

- COLOR TV TYPE
- MULTI-FUNCTION
- VERTICAL OUTPUT PENTODE
- 10 WATTS PLATE DISSIPATION
- VERTICAL OSCILLATOR
- SYNC CLIPPER

The 6AK9 is a multifunction compactron containing two dissimilar triodes and a beam pentode. The pentode section is suitable for vertical-deflection amplifier service in medium-sized color television receivers. Triode Section 2 (pins 2, 3 and 7) has an amplification factor of 20 and is especially suited for vertical oscillator use. Triode Section 1 has an amplification factor of 43 and is well suited for sync-clipper applications.

6AL5—3AL5—12AL5

TWIN DIODE

DESCRIPTION AND RATING

The 6AL5 is a miniature high-perveance twin diode in which separate cathodes are provided for the two sections. The 6AL5 is suited for a wide variety of applications which include service as a detector in FM and television circuits, automatic-gain-control rectifier, or a low-current power rectifier. Each diode can be used independently of the other or combined in parallel or full-wave arrangements. The resonant frequency of each section of the 6AL5 is approximately 700 megacycles.

The 3AL5, 6AL5 and 12AL5 are alike except for heater ratings and heater-cathode voltage ratings. In addition, the 3AL5, as a result of its controlled heater warm-up characteristic, is suited for use in television receivers which employ series-connected heaters. When the 3AL5 is used in conjunction with other 600-milliampere types which exhibit essentially the same heater warm-up characteristic, heater voltage surges across the individual tubes are minimized during the warm-up period.

Electronic TUBES

6AM4

TRIODE

FOR UHF MIXER AND AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 6AM4 is a miniature high-mu triode designed for use as a grounded-grid mixer or amplifier in television receivers that operate in the ultra-high-frequency region. Its sharp-cutoff and high transconductance, coupled with its excellent isolation between input and output, make the 6AM4 well suited for grounded-grid mixer or amplifier service over the entire range of VHF-UHF television frequencies.

6AQ5—5AQ5

BEAM PENTODE

DESCRIPTION AND RATING

The 6AQ5 is a miniature beam-power pentode designed for use in the audio-frequency power output stage of television and radio receivers. It may also be used as a triode-connected vertical deflection amplifier in television receivers. Within its maximum ratings, the performance of the 6AQ5 is equivalent to that of the 6V6-GT.

Except for heater ratings, the 5AQ5 is identical to the 6AQ5. In addition, the 5AQ5, as a result of its controlled heater warm-up characteristic, is especially suited for use in television receivers which employ series-connected heaters. When the 5AQ5 is used in conjunction with other 600-milliampere types which exhibit essentially the same heater warm-up characteristic, heater voltage surges across the individual tubes are minimized during the warm-up period.

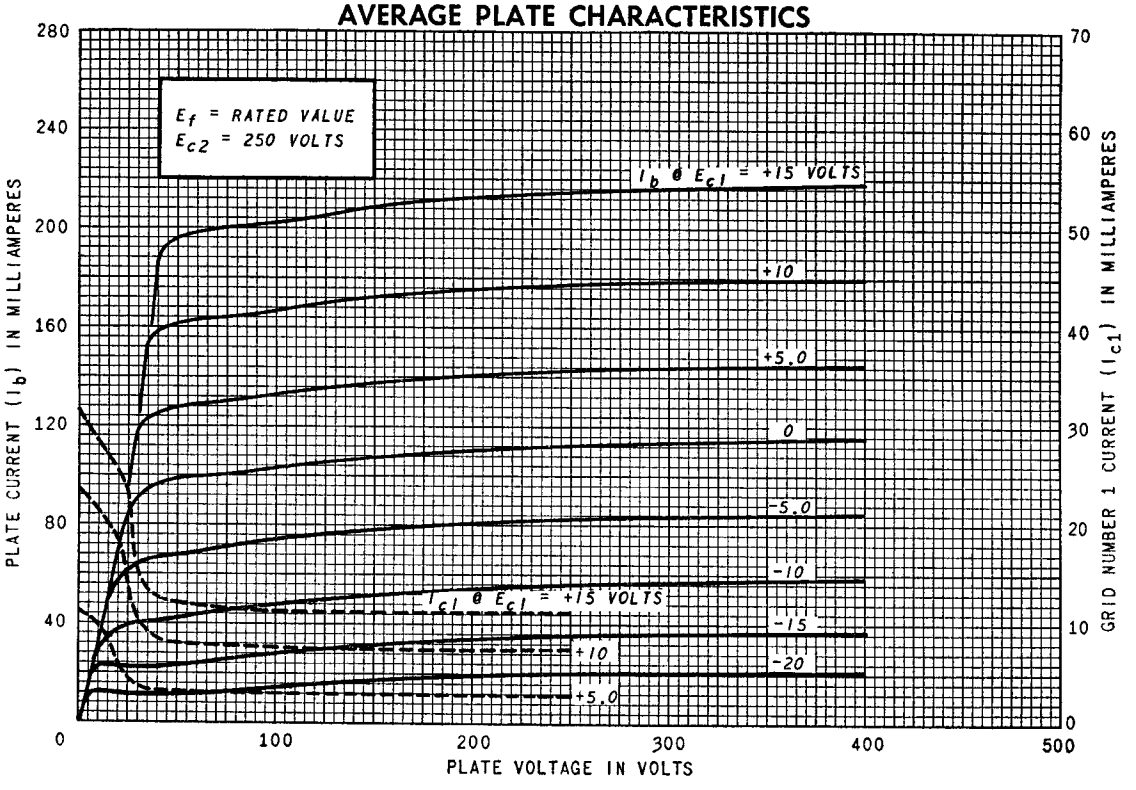
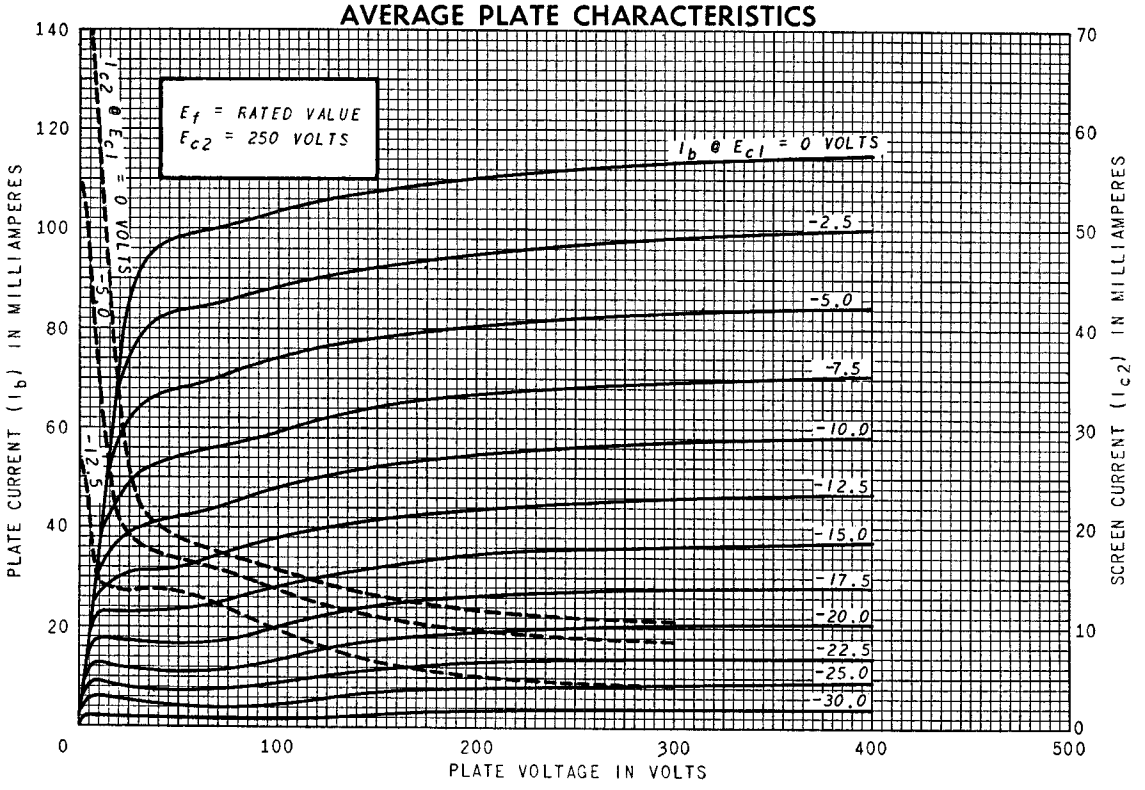
* Heater warm-up time is defined as the time required in the circuit shown at the right for the voltage across the heater terminals to increase from zero to the heater test voltage (V_1). For this type, E = 18.7 volts (RMS or DC), V_1 = 3.73 volts (RMS or DC), and R = 23.5 ohms.



† Without external shield.
‡ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.
§ With screen tied to plate.



π Value given is to be considered as an Absolute Maximum Rating. In this case, the combined effect of supply voltage variation, manufacturing variation including components in the equipment, and adjustment of equipment controls should not cause the rated value to be exceeded.

▲ In stages operating with grid-leak bias, an adequate cathode-bias resistor or other suitable means is required to protect the tube in the absence of excitation.

Electronic TUBES

6AR8

SHEET-BEAM TUBE

FOR TV SYNCHRONOUS DETECTOR AND BURST GATE APPLICATIONS

DESCRIPTION AND RATING

The 6AR8 is a miniature double-plate sheet-beam tube which incorporates a pair of balanced deflectors to direct the electron beam to either of the two plates and a control grid to vary the intensity of the beam. The resulting unique characteristics of this tube make it especially suited for service as a synchronous detector in color television receivers. In this application, relatively large, balanced output signals of both positive and negative polarities are developed which eliminate the need for phase-inversion functions in the matrix circuits. Other features of the 6AR8 synchronous detector circuit include low oscillator injection power requirements, freedom from the space-charge coupling effects which are present in dual-control pentodes and heptodes, linear output voltages, insensitiveness to variations in oscillator amplitude over a wide range, and a high ratio of plate to accelerator current. The 6AR8 is also suitable for service in the burst gate circuit of color TV receivers and a variety of other switching and gating applications.

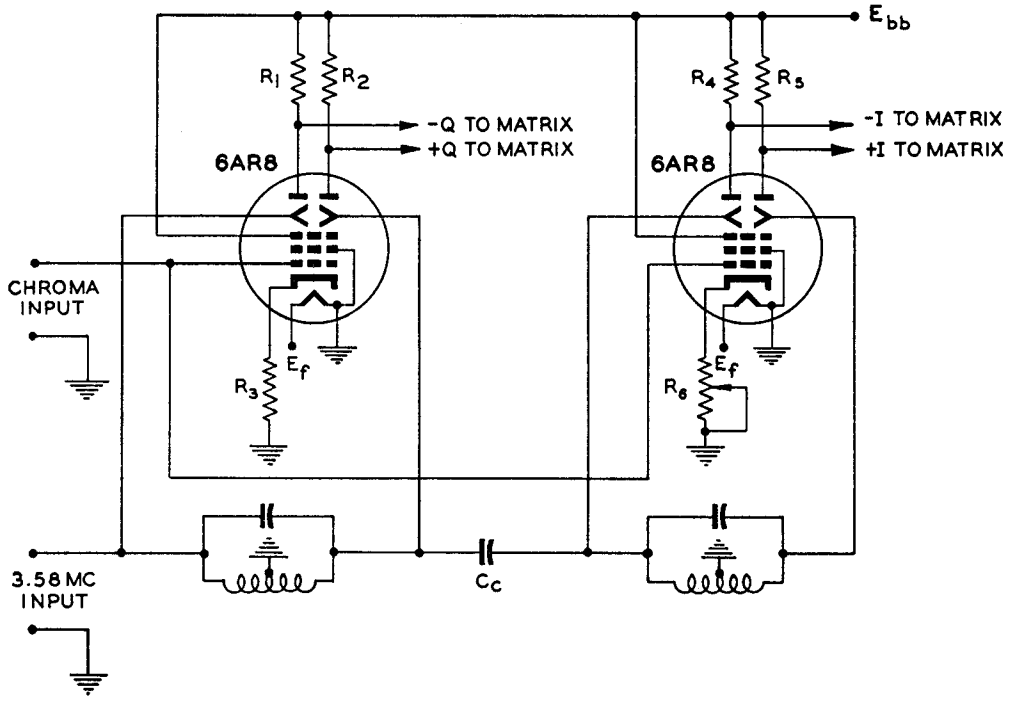
* Without external shield.
† Pin 5 should be connected directly to ground.
‡ Deflector switching voltage is defined as the total voltage change on either deflector with an equal and opposite change on the other deflector required to switch the plate current from one plate to the other.
Note: The 6AR8 should be so located in the receiver that it is not subjected to stray magnetic fields.

CROSS-SECTION SCHEMATIC DIAGRAM OF THE 6AR8

OPERATING CONSIDERATIONS FOR THE 6AR8



A cross-section schematic diagram of the construction of the 6AR8 is shown. In this tube, the electrons pass from the cathode to either of the two plates in the form of a planar beam or "sheet." Before the electron stream emerges from the openings in the accelerator structure, it is acted on by the focus electrodes and the control grid. The focus electrode tends to converge the electrons into the required sheet beam, while the conventional grid-number 1 structure which surrounds the cathode serves to control the intensity of the beam.

Between the accelerator and the plates the electron beam passes between the deflector electrodes. Depending on the voltages applied to the deflectors, the beam will be directed entirely to either one or the other of the two plates or proportioned between them. The internal shield, located between the two plates, acts to suppress the interchange of secondary-emission electrons between the plates. The suppressor and the focus electrodes are internally connected to one side of the heater.

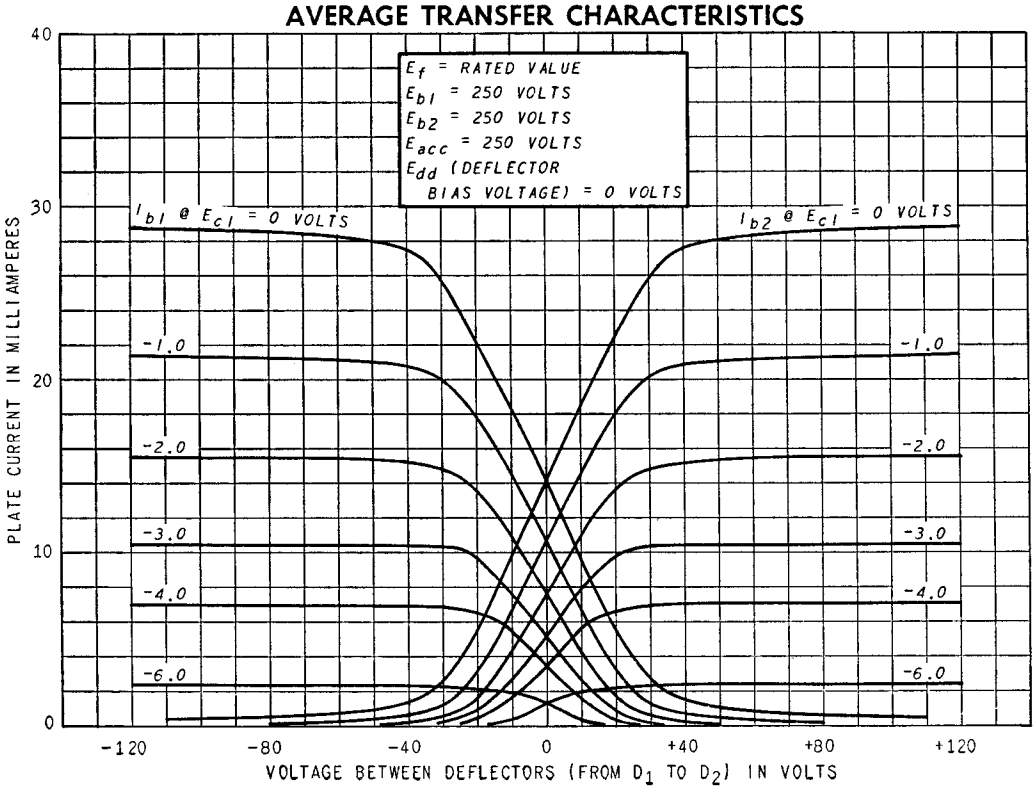
In normal operation, positive d-c voltages are applied to the accelerator and plates, and signal voltages are applied to the deflectors and control grid. The frequency of the signal applied to the deflectors determines the rate at which the plate current is switched between the two plates; the grid-number 1 voltage varies the magnitude of the plate current. The interesting tube characteristics which result from the unique construction of the 6AR8 are indicated by the average tube characteristic curves which follow. The tube may be considered as equivalent to a voltage-controlled single-pole double-throw switch through which a current, the magnitude of which is also voltage-controlled, flows.

If both plates and the accelerator are operated at +250 volts and a cathode-bias resistor of 300 ohms is employed, the deflectors require a peak switching voltage of 20 volts (or a peak voltage difference between deflectors of 40 volts) maximum to switch the plate current from one plate to the other. In a practical circuit, however, in which the deflectors are driven in push-pull with the center-tap of the source grounded, a somewhat higher value of deflector drive voltage must be used. The increased drive voltage is required to allow for those tubes in which the switching characteristics are somewhat offset with respect to zero voltage difference between deflectors.

For an accelerator voltage of +250 volts, the minimum deflector switching voltage occurs at a d-c deflector bias of approximately −8 volts; however, the d-c deflector bias is not particularly critical for focus as the deflection sensitivity

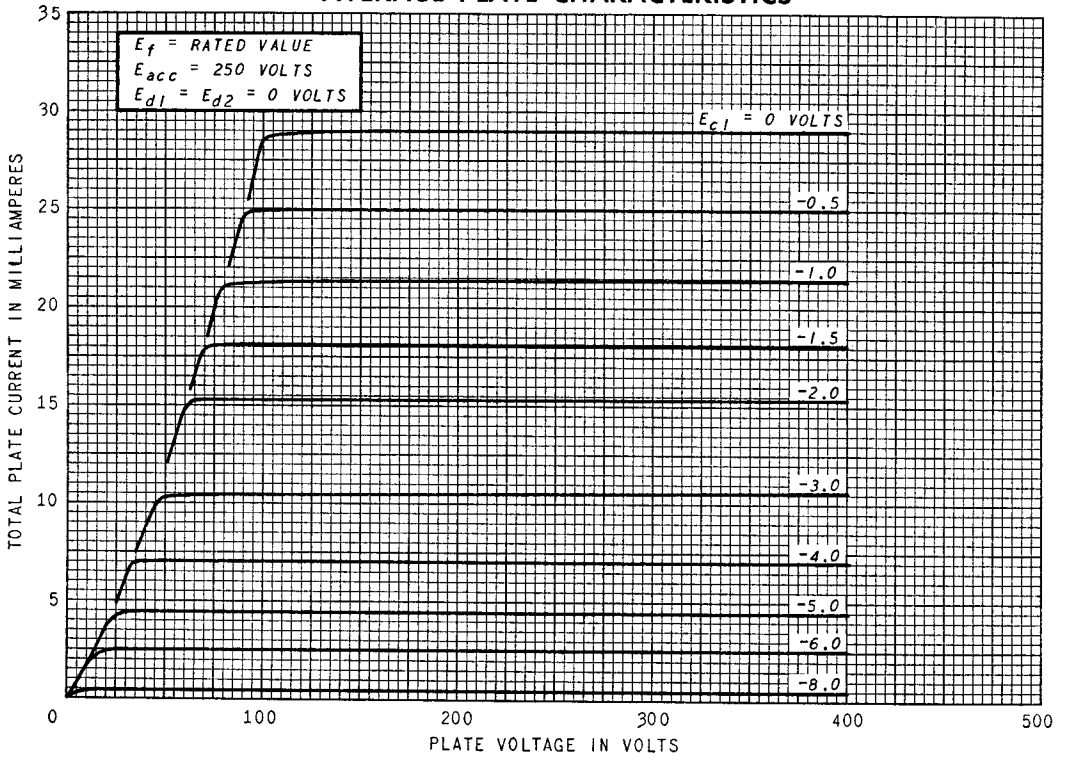
CIRCUIT DIAGRAM OF TWO 6AR8 TUBES USED AS SYNCHRONOUS DETECTORS

OPERATING CONSIDERATIONS FOR THE 6AR8 (Cont'd)



characteristic exhibits a broad maximum. Care should be exercised, nevertheless, to assure that defocusing effects are not present whenever the tube is operated at conditions other than those recommended.

The circuit diagram for two 6AR8 tubes employed as synchronous detectorsπ in a color television receiver is shown. In this arrangement, positive voltages are applied directly to the accelerator grids and through load resistors R1, R2, R4 and R5 to each of the plates. The chrominance signal is applied to the control grid of each tube. The 3.58-megacycle reference signal is applied in push-pull between the deflectors of each tube. The small coupling capacitor, Cc, between the tuned driving circuits provides the necessary 90-degree phase shift for the I and Q detectors. Also each tube is biased with a cathode resistor, R3 and R6; resistor R6 is variable so that the relative gains of the two demodulators can be adjusted.



In principle, the 6AR8 circuit is a product-demodulator type of synchronous detector; however, because the circuit uses a double-plate sheet-beam tube rather than a dual-control pentode or heptode, certain significant operating features result. First the 6AR8 circuit is capable of delivering relatively large and balanced output voltages which exhibit good linearity. Because output voltages are available of both positive and negative polarities, the need for the incorporation of phase-inverter circuits in the matrix section of the color receiver is completely eliminated. Also, providing the oscillator reference voltage is adequate to switch the plate currents between the two plates, the circuit is insensitive to variations in the amplitude of the oscillator voltage over a wide range. Furthermore, unlike the pentode or heptode synchronous detector circuits in which the third grid is driven positive by the oscillator reference voltage, the deflectors of the 6AR8 require very little excitation power. Consequently, less power is required from the 3.85-megacycle reference oscillator in the sheet-beam tube circuit.

Another feature is that space-charge coupling effects, which are inherently present in dual-control pentodes and heptodes, are unnoticeable in the 6AR8. Also, unlike most dual-control pentodes and heptodes in which the screen current is an appreciable percent of the plate current, the accelerator current of the 6AR8 is less than one-twentieth of its plate current.

Design-Center ratings are limiting values of operating and environmental conditions applicable to a bogey tube of a specified type as defined by its published data, and should not be exceeded under normal conditions.

These values are chosen by the tube manufacturer to provide acceptable serviceability of the tube in average applications, taking responsibility for normal changes in operating conditions due to rated supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all tubes.

The equipment manufacturer should design so that initially no design-center value for the intended service is exceeded with a bogey tube in equipment operating at the stated normal supply-voltage.

6AU4-GTA—19AU4-GTA

DIODE

FOR TV DAMPING DIODE APPLICATIONS

DESCRIPTION AND RATING

The 6AU4-GTA is a single heater-cathode type diode intended for service as the damping diode in the horizontal-deflection circuit of television receivers. Its high output current capabilities make the tube particularly well suited for operation in conjunction with the 6CD6-GA in autotransformer deflection systems. Except for increased maximum d-c output current and peak plate current ratings, the 6AU4-GTA is identical to the 6AU4-GT.

The 19AU4-GTA differs from the 6AU4-GTA by incorporating different heater ratings. In addition, the 19AU4-GTA as a result of its controlled heater warm-up characteristic, is especially suited for use in television receivers which employ series-connected heaters. When used in conjunction with other 600-milliampere types which exhibit essentially the same heater warm-up characteristic, heater voltage surges across the individual tubes are minimized during the warm-up period.

Electronic TUBES

6AU8-A

TRIODE—PENTODE

DESCRIPTION AND RATING

The 6AU8-A is a general-purpose miniature tube which contains a sharp-cut-off pentode and a medium-mu triode in one envelope. Each section has a separate cathode and is electrically independent.

The tube is suitable for a wide variety of general-purpose applications in both monochrome and color television receivers. The high figure of merit of the pentode section makes it particularly suited for service as a video amplifier, video intermediate-frequency amplifier, and sound intermediate-frequency amplifier. The triode section is intended for use as a sync amplifier, separator, or clipper, or as a sweep oscillator. The triode section may also be connected as a diode for video-detector applications, which adds to the over-all versatility of the tube.

In addition, the 6AU8-A, as a result of its controlled heater warm-up characteristic, is especially suited for use in television receivers that employ series-connected heaters. The 6AU8-A differs from the 6AU8 primarily by incorporating a controlled plate-knee characteristic.

MAXIMUM RATINGS (Cont'd)

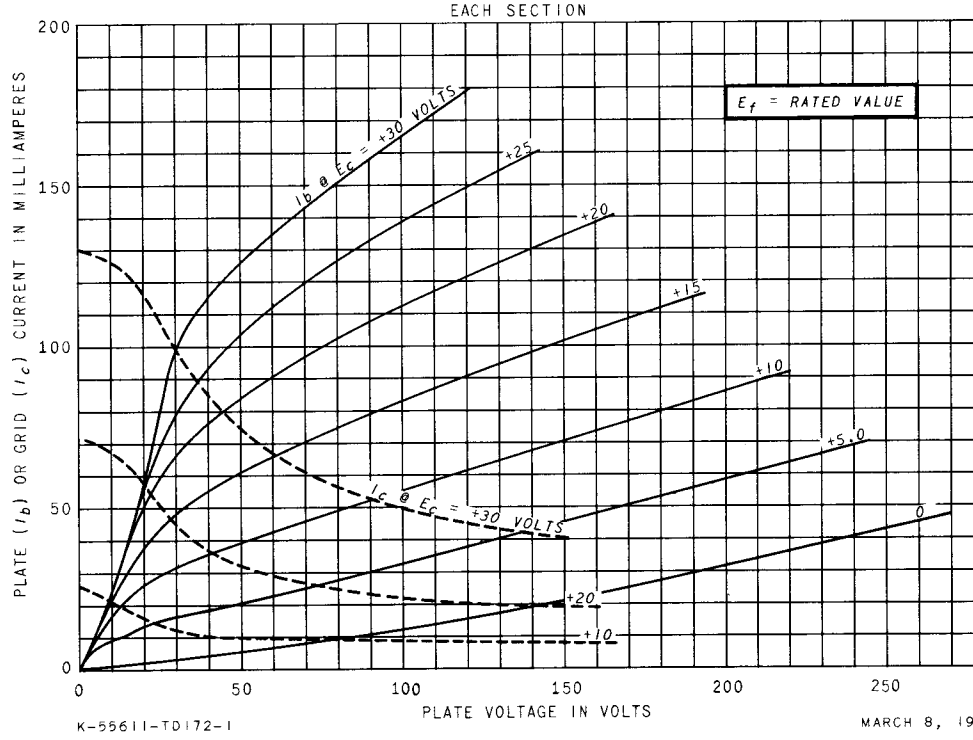
Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

CHARACTERISTICS AND TYPICAL OPERATION

Average Characteristics, Each Section			
Plate Voltage	100	250	Volts
Grid Voltage	0	−8.5	Volts
Amplification Factor	20	17	
Plate Resistance, approximate	6500	7700	Ohms
Transconductance	3100	2200	Micromhos
Plate Current	11.8	10.5	Milliamperes
Grid Voltage, approximate Ib = 10 Microamperes	....	−24	Volts



† The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

‡ Heater current of a bogey tube at Ef = 6.3 volts.

§ Without external shield.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

BEAM PENTODE

FOR TV HORIZONTAL-DEFLECTION AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 6AV5-GA is a beam pentode designed primarily for use as the horizontal-deflection amplifier in television receivers. The tube exhibits high perveance, high plate current at low plate and screen voltages, and a high ratio of plate to screen current.

Except for heater ratings, the 12AV5-GA, 17AV5-GA, and 25AV5-GA are identical to the 6AV5-GA. In addition, the 12AV5-GA and 17AV5-GA, which feature a controlled heater warm-up characteristic, are especially suited for use in television receivers with series-connected heaters.

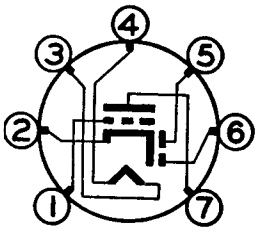
6AV6—3AV6—12AV6



DUPLEX-DIODE TRIODE

DESCRIPTION AND RATING

The 6AV6 is a miniature duplex-diode, high-mu triode intended primarily for use as a combined detector, amplifier, and automatic-volume-control tube in radio receivers. The triode section incorporates a high amplification factor and is capable of providing a relatively large undistorted output voltage from a very small input signal.

The 3AV6, 6AV6, and 12AV6 are alike except for heater ratings and heater-cathode voltage ratings. The 12AV6 is particularly suited for use in a-c/d-c radio receivers. The 3AV6, as a result of its controlled heater warm-up characteristic, is especially well suited for use in television receivers which employ series-connected heaters. When the 3AV6 is used in conjunction with other 600-milliampere types which exhibit essentially the same heater warm-up characteristic, heater voltage surges across the individual tubes are minimized during the warm-up period.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Electronic TUBES

6AX4-GTB

DIODE

FOR TV DAMPING DIODE APPLICATIONS

DESCRIPTION AND RATING

The 6AX4-GTB is a single heater-cathode type diode for service as the damping diode in the horizontal-deflection circuit of television receivers. It will withstand high pulse voltages between the heater and cathode and high inverse pulse voltages between the plate and cathode. These characteristics make the tube particularly useful in autotransformer deflection systems in which high pulse voltages are applied to the cathode of the damper tube.

The 6AX4-GTB is unilaterally interchangeable with the 6AX4-GT and 6AX4-GTA. It differs from the 6AX4-GTA in having a higher peak inverse plate voltage rating.

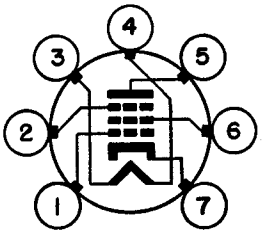
6BA6—3BA6—4BA6—12BA6

PENTODE

FOR RF AND IF AMPLIFIER APPLICATIONS



DESCRIPTION AND RATING

The 6BA6 is a miniature remote-cutoff pentode primarily designed for use as a high-gain radio-frequency or intermediate-frequency amplifier. Features include small size, low grid-plate capacitance, and high transconductance.

Except for heater ratings the 3BA6 and 4BA6 are identical to the 6BA6. In addition, they incorporate a controlled heater-warm-up characteristic which makes them especially suited for use in television receivers that employ series-connected heaters.

The 12BA6, which differs from the 6BA6 only in heater ratings and heater-cathode voltage ratings, is especially useful in a-c/d-c radio receivers.

6BD11

COMPACTRON DISSIMILAR-DOUBLE-TRIODE PENTODE

DESCRIPTION AND RATING

The 6BD11 is a compactron containing a high-mu triode, a medium-mu triode, and a sharp-cutoff pentode. The high-mu triode is intended for general-purpose use, the medium-mu triode for sync separator service, and the pentode for video amplifier service.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

6BE6—3BE6—4BE6—12BE6

HEPTODE

FOR PENTAGRID CONVERTER APPLICATIONS

DESCRIPTION AND RATING

The 6BE6 is a miniature heptode primarily designed to perform the combined functions of the mixer and oscillator in superheterodyne circuits in both the standard broadcast and FM bands. Its performance in these applications is characterized by high conversion gain and a high degree of oscillator stability with variations in the applied automatic-volume-control bias voltage.

Except for heater ratings, the 3BE6 and 4BE6 are identical to the 6BE6. In addition, they incorporate a controlled heater-warm-up characteristic which makes them especially suited for use in radio or television receivers that employ series-connected heaters.

The 12BE6, which differs from the 6BE6 only in heater ratings and heater-cathode voltage ratings, is especially useful in a-c/d-c radio receivers.

Compactron
Dissimilar Double Pentode

6BF11

- AUDIO POWER PENTODE
- QUADRATURE FM DETECTOR
- LOW HUM
- 140 VOLTS B+

The 6BF11 is a compactron containing a sharp-cutoff, dual-control pentode (Section 2) and a power pentode (Section 1). The dual-control pentode is intended for use as an FM detector and the power pentode as an audio-frequency output amplifier in television receivers. The power output pentode features relatively high dynamic plate resistance which results in minimizing hum currents in the plate circuit due to power supply ripple.

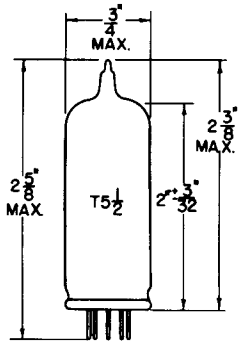
Description and Rating



BEAM POWER AMPLIFIER

GENERAL DESCRIPTION

Principal Application: The 6BF5 is a miniature beam-power amplifier designed for use in the audio output stage of television and broadcast receivers. The 6BF5 features high sensitivity and is capable of delivering relatively high power output at low plate and screen voltages. When connected as a triode, the 6BF5 may be used as a vertical-deflection amplifier in television receivers.

6BG6-GA — 19BG6-GA

BEAM PENTODE

FOR TV HORIZONTAL-DEFLECTION AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 6BG6-GA is a beam-power pentode designed primarily for use as the horizontal deflection amplifier in television receivers. Electrically and physically, the 6BG6-GA is a replacement for the 6BG6-G; the 6BG6-GA differs primarily from the 6BG6-G by employing a straight-sided T-12 envelope.

Except for heater ratings, the 19BG6-GA is identical to the 6BG6-GA.

Electronic TUBES

6BH8

TRIODE-PENTODE

DESCRIPTION AND RATING

The 6BH8 is a general-purpose miniature tube which contains a sharp-cutoff pentode and a medium-mu triode in one envelope. Except for the electrical characteristics of the triode section, the 6BH8 is identical to the 6AU8. The triode section of the 6BH8 incorporates a lower amplification factor than the 6AU8 triode section and consequently may be used in applications where the lower amplification factor is desired.

Like the 6AU8, the tube is suitable for a wide variety of general-purpose applications in both monochrome and color television receivers. The high figure of merit of the pentode section makes it particularly suited for service as a video amplifier, video intermediate-frequency amplifier, and sound intermediate-frequency amplifier. The triode section is intended for use as a sync amplifier, separator, or clipper or as a sweep oscillator. The triode section may also be connected as a diode for video-detector applications, which adds to the over-all versatility of the tube.

In addition, the 6BH8, as a result of its controlled heater warm-up characteristic, is especially suited for use in television receivers which employ series-connected heaters. When the tube is used in conjunction with other 600-milliampere types which exhibit essentially the same heater warm-up characteristic, heater voltage surges across the individual tubes are minimized during the warm-up period.

6BJ7

TRIPLE DIODE

FOR TV DC-RESTORER APPLICATIONS

DESCRIPTION AND RATING

The 6BJ7 is a miniature, triple diode primarily intended for use as a d-c restorer in each of the three signal channels of color television receivers. For flexibility in circuit design, each diode incorporates a separate cathode. The electrical characteristics of each section of the 6BJ7 are similar to those of each section of the 6AL5.

6BK5—12BK5—25BK5

BEAM PENTODE

DESCRIPTION AND RATING

The 6BK5 is a miniature beam pentode designed primarily for use in the audio-frequency power output stage of television and radio receivers in which only small driving voltages are available. Features of the tube include extremely high power sensitivity, high transconductance, and high plate efficiency.

Except for heater ratings and heater-cathode voltage ratings, the 12BK5 is identical to the 6BK5. The 12BK5, as a result of its controlled heater warm-up characteristic, is especially suited for use in television receivers which employ series-connected heaters. When the 12BK5 is used in conjunction with other 600-milliampere types which exhibit essentially the same heater warm-up characteristic, heater voltage surges across the individual tubes are minimized during the warm-up period.

The 25BK5 differs from the 6BK5 only in heater ratings.

6BK7-B

TWIN TRIODE

DESCRIPTION AND RATING

The 6BK7-B is a miniature twin triode designed primarily for use as a cascode amplifier at frequencies below approximately 300 megacycles. It is especially useful as the radio-frequency amplifier in very-high-frequency television tuners or as the intermediate-frequency preamplifier in ultra-high-frequency tuners. Its performance as a cascode amplifier is characterized by high gain and low noise figure. Electrically and physically, the 6BK7-B is a replacement for the 6BK7 and the 6BK7-A.

* The time required for the voltage across the heater to reach 80 percent of its rated value after applying 4 times rated heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the rated heater voltage divided by the rated heater current.

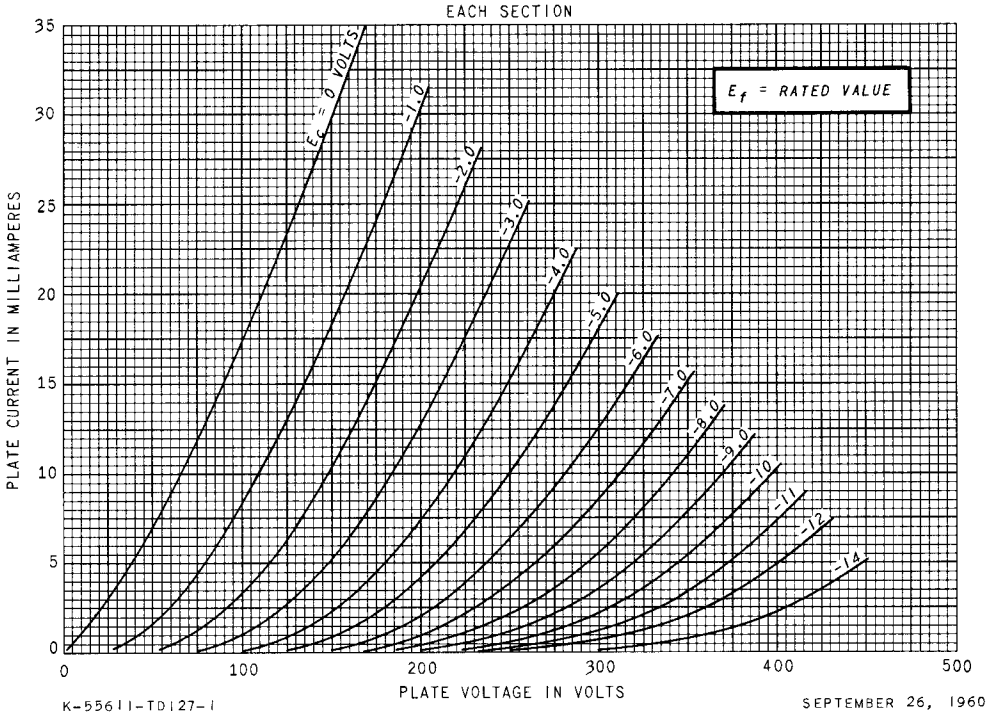
† Without external shield.

‡ It is recommended that pin 9 be grounded.

§ When the tube is used as a cascode amplifier and the two sections are connected in series, this voltage may be as high as 300 volts maximum under cutoff conditions.

π As measured in a cascode amplifier which has a balanced 300-ohm input system and which operates at a plate supply voltage of 250 volts, a plate current of 18 milliamperes, a frequency of 200 megacycles, a stage bandwidth of 7 megacycles, and an effective noise bandwidth of 3.5 megacycles.

Design-Center ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under normal conditions.



The tube manufacturer chooses these values to provide acceptable serviceability of the tube in average applications, making allowance for normal changes in operating conditions due to rated supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially no design-center value for the intended service is exceeded with a bogey tube under normal operating conditions at the stated normal supply voltage.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

6BN4—2BN4—3BN4

TRIODE

FOR VHF TV RADIO-FREQUENCY AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 6BN4 is a miniature medium-mu triode primarily intended for use as a radio-frequency amplifier in VHF television tuners. The electrical characteristics of the 6BN4 are similar to those of each section of the 6BZ7.

Except for heater ratings, the 2BN4 and 3BN4 are identical to the 6BN4. In addition, they incorporate a controlled heater-warm-up characteristic which makes them especially suited for use in television receivers that employ series-connected heaters.

GENERAL

ELECTRICAL

Cathode—Coated Unipotential	2BN4	3BN4	6BN4
Heater Voltage, AC or DC	2.3	3.0	6.3 ± 10% Volts
Heater Current	0.6 ± 6%	0.45 ± 6%	0.2 Amperes
Heater Warm-up Time*	11	11	.... Seconds

GATED-BEAM DISCRIMINATOR

FOR FM AND TV LIMITER AND DISCRIMINATOR APPLICATIONS

DESCRIPTION AND RATING

The 6BN6 is a miniature beam tube primarily designed to perform the combined functions of the limiter, discriminator, and audio-voltage amplifier in FM and intercarrier television receivers. Advantages inherent in this application of the 6BN6 include excellent performance, circuit simplicity, and ease of alignment. Additional applications of the tube include use as a limiter or as a sync-clipper.

Except for heater ratings and heater-cathode voltage ratings, the 3BN6 and 4BN6 are identical to the 6BN6. As a result of their controlled heater-warm-up characteristic, the 3BN6 and 4BN6 are especially suited for use in television receivers that employ series-connected heaters.

The 12BN6 is identical to the 6BN6 except for heater ratings.

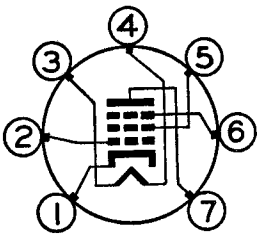
Design-Maximun ratings are limiting values of operating and environmental conditions applicable to a bogey tube of a specified type as defined by its published data, and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, taking responsibility for the effects of changes in operating conditions due to variations in tube characteristics.



The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, and environmental conditions.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

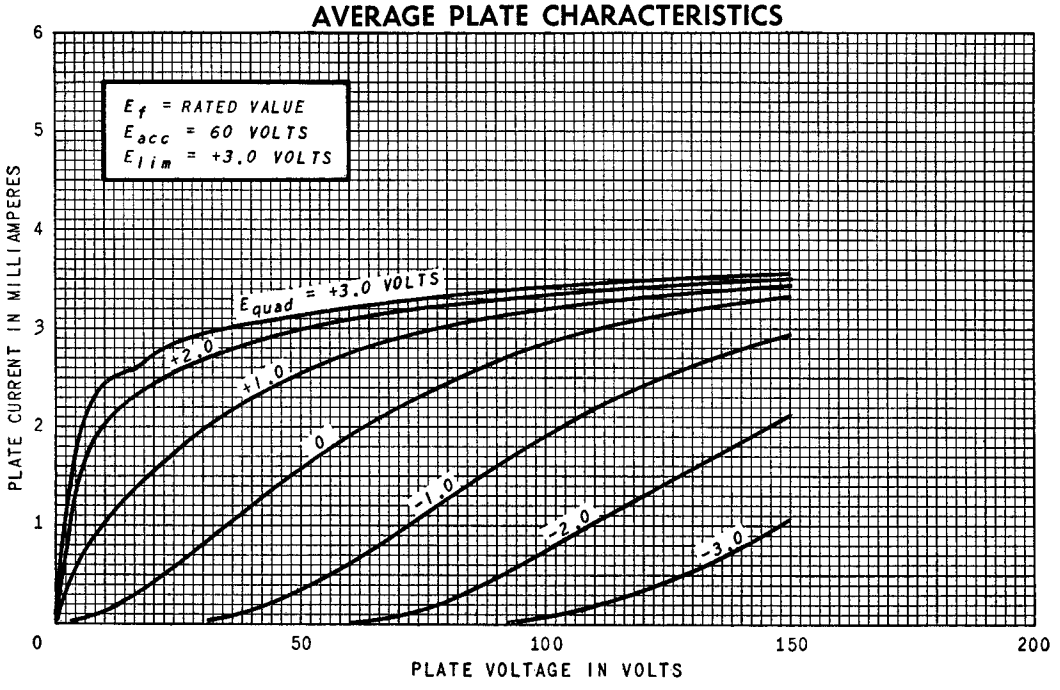
* The time required for the voltage across the heater to reach 80 percent of its rated value after applying 4 times rated heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the rated heater voltage divided by the rated heater current.

† Without external shield.

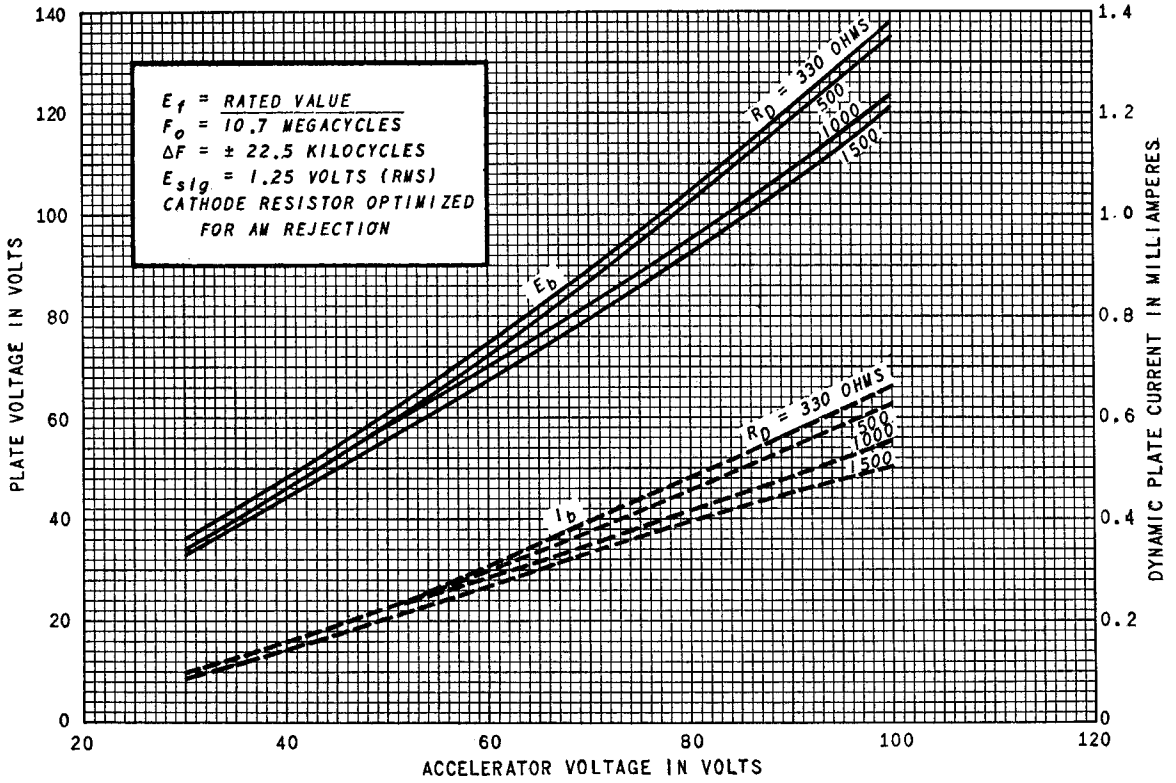
‡ The cathode resistor should be adjusted for maximum AM rejection in the output of the limiter-discriminator stage at the specified signal level. AM rejection is measured with an applied signal containing 30-percent amplitude modulation and 30-percent frequency modulation.



§ At signal levels above specified value, limiting is within ±2 decibels.

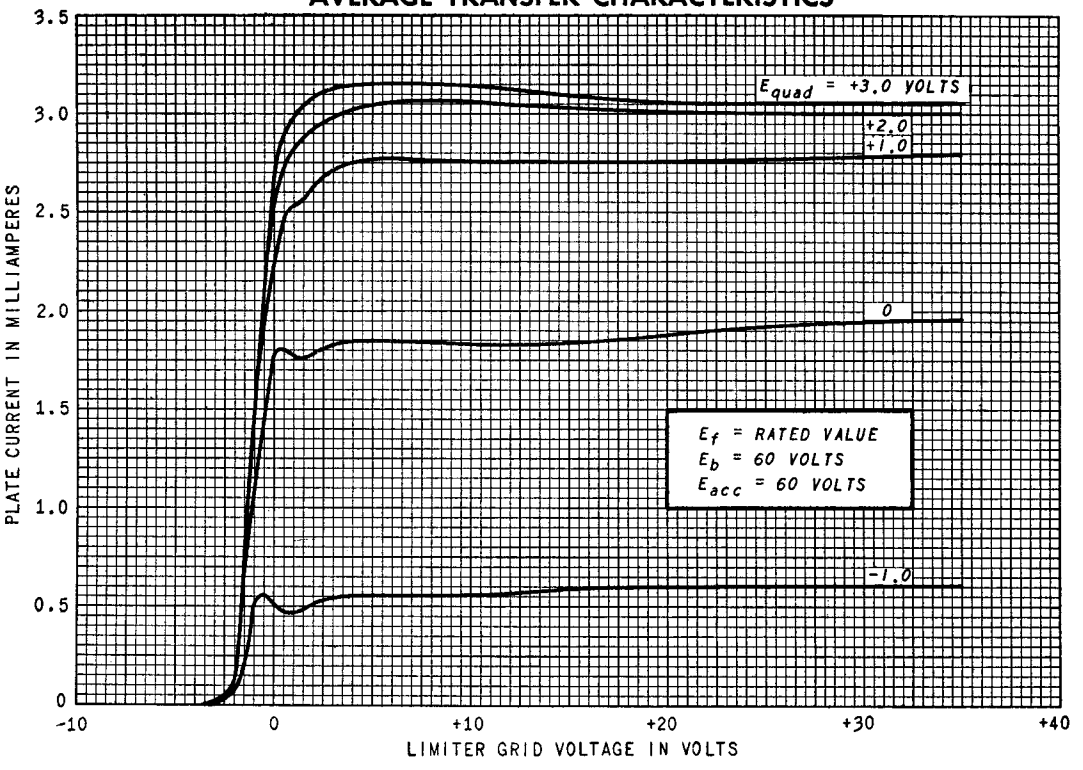
Adequate shielding between components of the limiter grid and the quadrature grid must be used to insure proper phasing of the voltage developed on the quadrature grid.

Standard de-emphasis requirements for FM are included.

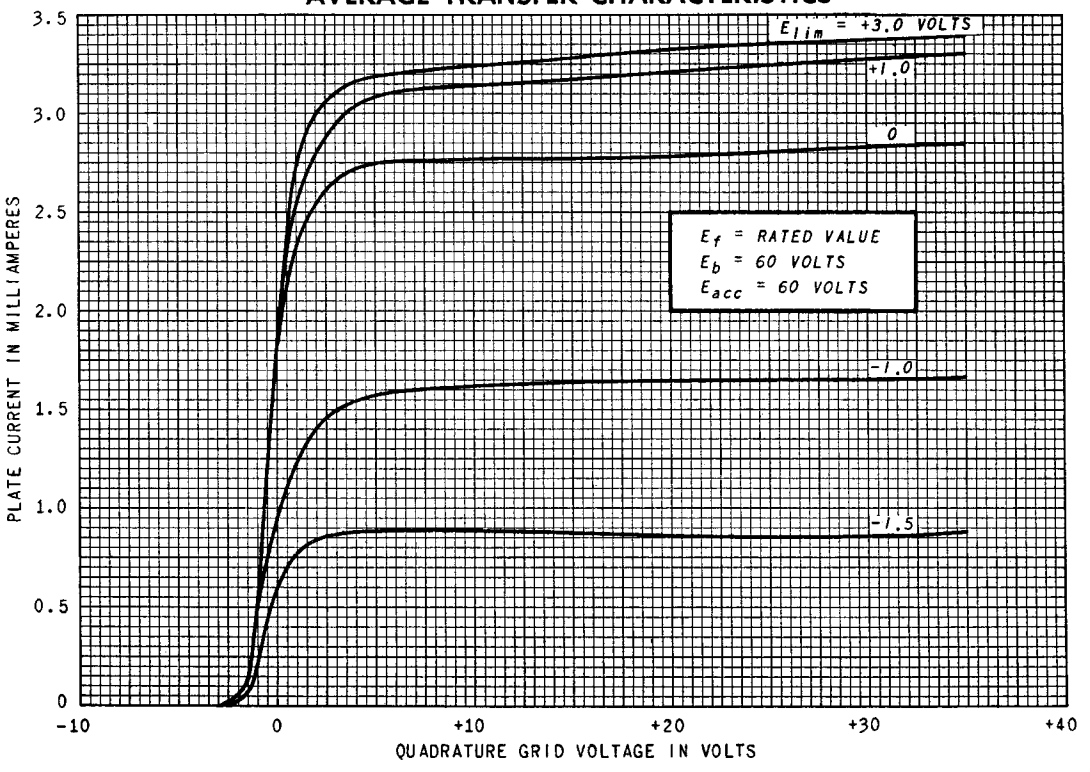


The Q of the quadrature grid circuit should be high enough to develop a minimum of 4 volts (RMS) signal with 2 volts (RMS) of the center-frequency signal applied to the limiter grid. It is recommended that the coil be shunted by a minimum of 10 $\mu\mu$f. The capacitance may be composed of tube input capacitance, stray capacitance, and distributed capacitance, as well as physical capacitance.

AVERAGE PLATE CHARACTERISTICS



OPERATION CHARACTERISTICS



To obtain the optimum dial-tuning characteristic (a symmetrical discriminator response curve) in FM applications, it is essential that the ratio of plate current with no signal to plate current with an unmodulated signal should equal unity. After a value of accelerator voltage is chosen, the plate voltage applied to the tube should be chosen as indicated by the following graph in order to realize this unity ratio of plate current. The graph also shows the average dynamic plate current that is flowing under the specified plate and accelerator voltage conditions. The plate load resistor should be chosen to drop the plate supply voltage to the specified plate voltage.

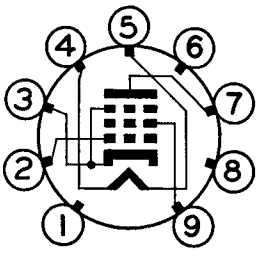
Design-Center ratings are limiting values of operating conditions applicable to a bogey tube of a specified type as defined by its published data, and should not be exceeded under normal conditions.



The tube manufacturer chooses these values to provide acceptable serviceability of the tube in average applications, taking responsibility for normal changes in operating conditions due to rated supply voltage variation (For an AC power source, 117 volts plus or minus 10% is accepted USA practice.), equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in tube characteristics.

The equipment manufacturer should design so that initially no design-center value for the intended service is exceeded with a bogey tube in equipment operating at the stated normal supply voltage.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

BEAM PENTODE

FOR TV HORIZONTAL-DEFLECTION AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 6BQ6-GA is a beam-power pentode designed primarily for use as horizontal-deflection amplifier in television receivers. The tube exhibits high perveance, high plate current at low plate and screen voltages, and a high ratio of plate to screen current.

Except for heater ratings, the 12BQ6-GA and 25BQ6-GA are identical to the 6BQ6-GA. In addition, the 12BQ6-GA features a controlled heater warm-up characteristic to make it especially suited for use in television receivers which employ 600-milliampere, series-connected heaters.

TWIN TRIODE

FOR VHF CASCODE AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 6BQ7-A is a miniature, medium-mu twin triode primarily designed for use as a cascode, radio-frequency amplifier in very-high-frequency television tuners. In this application, its performance is characterized by high gain and low noise figure. An internal shield provides isolation between the two triode sections.

Except for heater ratings, the 4BQ7-A and 5BQ7-A are identical to the 6BQ7-A. In addition, as a result of their controlled heater warm-up characteristic, they are especially suited for use in television receivers that employ series-connected heaters.

TRIODE-PENTODE

FOR VHF CONVERTER APPLICATIONS

DESCRIPTION AND RATING

The 6BR8 is a miniature tube which contains a sharp-cutoff pentode and a medium-mu triode in one envelope. It is intended primarily for service as a combined triode oscillator and pentode mixer in VHF television tuners although the tube is also suitable for a wide variety of general-purpose applications in both monochrome and color television receivers. Except for basing arrangement and direct interelectrode capacitances, the 6BR8 is identical to the 6U8.

The 5BR8 is a 600-milliampere version of the 6BR8 which differs only in heater ratings. The 5BR8 exhibits a controlled heater warm-up characteristic which makes it particularly suited for use in television receivers which employ 600-milliampere series-connected heaters.

TWIN TRIODE

FOR VHF CASCODE AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 6BS8 is a miniature, medium-mu twin triode designed for use as a VHF cascode amplifier. In this application, section two (pins 1, 2, and 3) is intended for the input section.

Except for heater ratings, the 4BS8 is identical to the 6BS8. In addition, the 4BS8 incorporates a controlled heater-warm-up characteristic which makes it especially suited for use in television receivers that employ series-connected heaters.

Electronic TUBES

6BU8 — 3BU8 — 4BU8

TWIN PENTODE

DESCRIPTION AND RATING

The 6BU8 is a miniature multisection tube that incorporates separate plates and number-3 grids for the two sections together with a common screen, number-1 grid, and cathode. The tube is intended for use as a combined sync-AGC tube in television receivers. In this service, when used in conjunction with suitable circuitry, one section of the 6BU8 functions as sync separator and sync clipper, while the other section is used to generate the automatic-gain-control voltage. In addition, by utilizing the common number-1 grid, noise pulses can be suppressed from both synchronizing and automatic-gain-control circuits.

Except for heater ratings, the 3BU8 and 4BU8 are identical to the 6BU8. In addition, they incorporate a controlled heater warm-up characteristic which makes them especially suited for use in television receivers that employ series-connected heaters.

MAXIMUM RATINGS

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

6BV8

DUPLEX-DIODE TRIODE

DESCRIPTION AND RATING

The 6BV8 is a miniature duplex-diode medium-mu triode in which separate cathode and plate connections are provided for each diode section. The tube is intended primarily for service as a combined synchronous detector and chrominance amplifier in color television receivers. The high perveance characteristic of the triode section adapts the tube particularly to this service. It is also suitable for use as a combined FM detector and audio-frequency voltage amplifier.

The 6BV8 is especially suited for use where series-connected heaters are employed since it has a 600-milliampere heater current and a controlled heater warm-up characteristic.

Compactron Diode

6BW3

FOR TV DAMPING DIODE APPLICATIONS

■ COLOR TV TYPE ■ DIFFUSION BONDED CATHODE ■ 5000 VOLTS DC ■ 175 MILLIAMPERES DC

The 6BW3 is a compactron containing a single heater-cathode type diode. It is intended for service as the damping diode in the horizontal deflection circuit of color television receivers.

The diffusion bonded cathode practically eliminates one of the major failure mechanisms in damping diodes, which is plate-to-cathode arcing caused by emissive particles being pulled from the cathode by the high electrostatic field.

6BW8

DUPLEX-DIODE PENTODE

DESCRIPTION AND RATING

The 6BW8 is a duplex-diode sharp-cutoff pentode in which separate cathodes are provided for the diode and pentode sections. The diode sections are primarily intended for use as a horizontal phase detector in television receivers. The pentode section is suitable for use as a sound intermediate-frequency amplifier, sound limiter, and automatic-gain-control keyer.

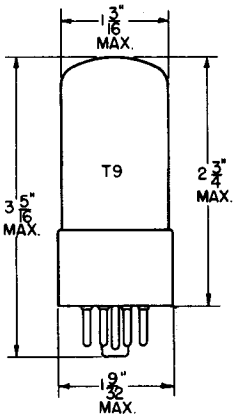
6BX7-GT
Description and Rating

TWIN TRIODE

GENERAL DESCRIPTION



Principal Application: The 6BX7-GT is a high-transconductance twin triode designed primarily for use as a combined vertical deflection amplifier and vertical oscillator in television receivers. Each section of the 6BX7-GT features high plate current at low plate voltages and is capable of withstanding the high pulse voltages normally encountered in this application. The 6BX7-GT, when operated from relatively low plate supply voltages, is capable of deflecting fully large-deflection-angle picture tubes.

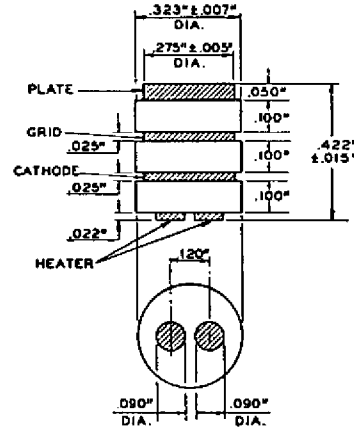
Electronic TUBES

6BY4

TRIODE

FOR UHF AMPLIFIER APPLICATIONS



DESCRIPTION AND RATING

The 6BY4 is a ceramic high-mu triode of parallel-plane construction designed primarily for use as a grounded-grid radio-frequency amplifier in combined UHF-VHF television tuners. In this service, at 900 megacycles, the 6BY4 exhibits a power gain of approximately 15 decibels and a noise factor of approximately 8.5 decibels with a 10-megacycle bandwidth. The high performance capabilities of the tube thus make possible simplified tuner designs in which the 6BY4 serves as the r-f amplifier for both the UHF and VHF bands. Special features of the tube include excellent isolation between input and output circuits, low lead inductances, low interelectrode capacitances, short transit time, extremely high ratio of transconductance to plate current, and small size.

The size of the 6BY4 makes it particularly suited to compact tuner designs. In these applications, the tube may be used with special clip-type or friction-type sockets which are either separate units or integral with the tuner; the 6BY4 may also be adapted to coaxial circuitry.

The special metal-ceramic construction of the 6BY4 provides several fundamental advantages over conventional glass receiving tubes. The tube may operate at much higher envelope temperatures, exhibits increased resistance to mechanical shock and vibration, has greatly increased physical strength, and produces significantly lower microphonic output. The 6BY4 construction is also well suited for use with printed circuit boards and other types of automatic circuit assembly.

6BY6—3BY6

HEPTODE

FOR GATED AMPLIFIER SERVICE

DESCRIPTION AND RATING

The 6BY6 is a miniature dual-control heptode designed primarily for use as a combined sync separator and sync clipper in television receivers. Each of the two independent control grids exhibits a sharp-cutoff characteristic.

Except for heater ratings, the 3BY6 is identical to the 6BY6. In addition as a result of its controlled heater warm-up characteristic, the 3BY6 is especially suited for use in television receivers which employ series-connected heaters. When the 3BY6 is used in conjunction with other 600-milliampere types which exhibit essentially the same heater warm-up characteristic, heater voltage surges across the individual tubes are minimized during the warm-up period.

6BZ7—4BZ7

TWIN TRIODE

FOR VHF CASCODE AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 6BZ7 is a miniature, medium-mu twin triode designed primarily for use as a cascode radio-frequency amplifier in very-high-frequency television tuners. In this application, its performance is characterized by high gain and low noise figure. An internal shield provides isolation between the two triode sections.

Except for heater ratings, the 4BZ7 is identical to the 6BZ7. In addition, as a result of its controlled heater warm-up characteristic, the 4BZ7 is especially suited for use in television receivers that employ 600-milliampere, series-connected heaters.

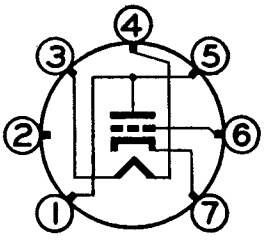
Design-Center ratings are limiting values of operating and environmental conditions applicable to a bogey tube of a specified type as defined by its published data, and should not be exceeded under normal conditions.

These values are chosen by the tube manufacturer to provide acceptable serviceability of the tube in average applications, taking responsibility for normal changes in operating conditions due to rated supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all tubes.



The equipment manufacturer should design so that initially no design-center value for the intended service is exceeded with a bogey tube in equipment operating at the stated normal supply voltage.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

6C10

TRIPLE TRIODE

The 6C10 is a compactron containing three high-mu triodes. Features of the device include separate pin connections for all three cathodes, grids, and plates, a button base, and a compact glass envelope. The 6C10 is especially suited for use in resistance-coupled voltage amplifiers, phase inverters, and numerous industrial-control circuits when high voltage-gain is desired.

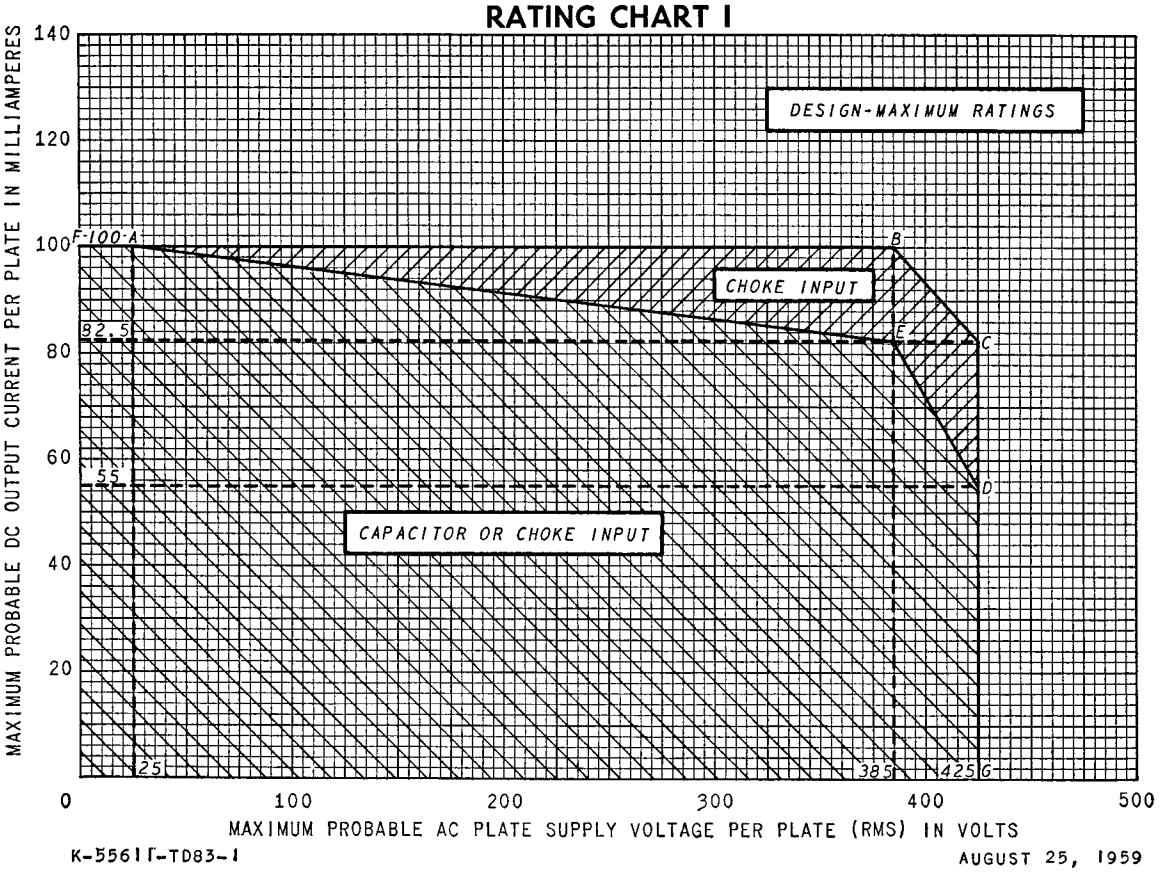
FULL-WAVE RECTIFIER WITH CAPACITOR-INPUT FILTER

AC Plate-Supply Voltage per Plate, RMS	250	300	350	Volts
Filter Input Capacitor	50	50	50	Microfarads
Total Plate-Supply Resistance per Plate	150	200	240	Ohms
DC Output Current	150	150	150	Milliamperes
DC Output Voltage at Filter Input	245	293	347	Volts

Tube Voltage Drop



Ib = 150 Milliamperes DC per Plate	20	Volts

To simplify the application of the maximum ratings to circuit design, the Design-Maximum ratings are presented in chart form as Rating Charts I, II, and III. Rating Chart I presents the maximum ratings for a-c plate supply voltage and d-c output current. Rating Chart II provides a convenient method for checking conformance with the maximum steady-state peak-plate-current rating. Rating Chart III offers a convenient method for checking conformance with the maximum transient peak-plate-current rating. Rating Chart I applies to both capacitor-input and choke-input filters, while Rating Charts II and III apply to capacitor-input filters only.

Operating points should be so selected that the boundary limits of a-c plate supply voltage and d-c output current on Rating Chart I, and maximum d-c output current per plate and rectification efficiency on Rating Chart II, are not exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, and environmental conditions. On Rating Chart I the boundary FAEDG defines the limits for capacitor-input filter operation, and the boundary FABCDG defines the limits for choke-input filter operation.

Rating Chart III shows the minimum value of plate supply resistance (R_s) required to remain within the transient peak-plate-current rating. The value of R_s should be such that it lies to the left of the line on Rating Chart III at the highest probable value of line voltage.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

6CB6-A
PENTODE

DESCRIPTION AND RATING

The 6CB6-A is a miniature pentode designed for use as a radio-frequency or intermediate-frequency amplifier in television receivers. Features of the tube include high transconductance and low interelectrode capacitances. The suppressor and cathode terminals are brought out to separate base pins to permit the use of an unbypassed cathode-bias resistor to minimize the effects of regeneration.

Electronic TUBES

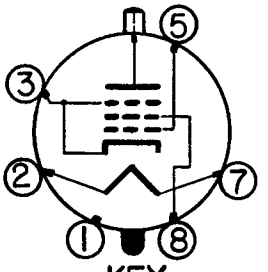
6CD6-GA—25CD6-GB

BEAM PENTODE

FOR TV HORIZONTAL-DEFLECTION AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 6CD6-GA is a beam-power pentode designed primarily for use as the horizontal-deflection amplifier in television receivers which incorporate large-deflection-angle picture tubes. Features of the tube include an extremely high perveance, high plate current at low plate and screen voltages, and a high ratio of plate to screen current. The 6CD6-GA may be used as a replacement for the 6CD6-G; it differs from the 6CD6-G by employing a straight-sided T-12 envelope and incorporating increased maximum ratings for plate dissipation, pulse plate voltage, and bulb temperature.



Except for heater ratings, the 25CD6-GB is identical to the 6CD6-GA. In addition, as a result of its controlled heater warm-up characteristic, the 25CD6-GB is especially suited for use in television receivers which employ series-connected heaters. When the 25CD6-GB is used in conjunction with other 600-milliampere types which exhibit essentially the same heater warm-up characteristic, heater voltage surges across the individual tubes are minimized during the warm-up period.

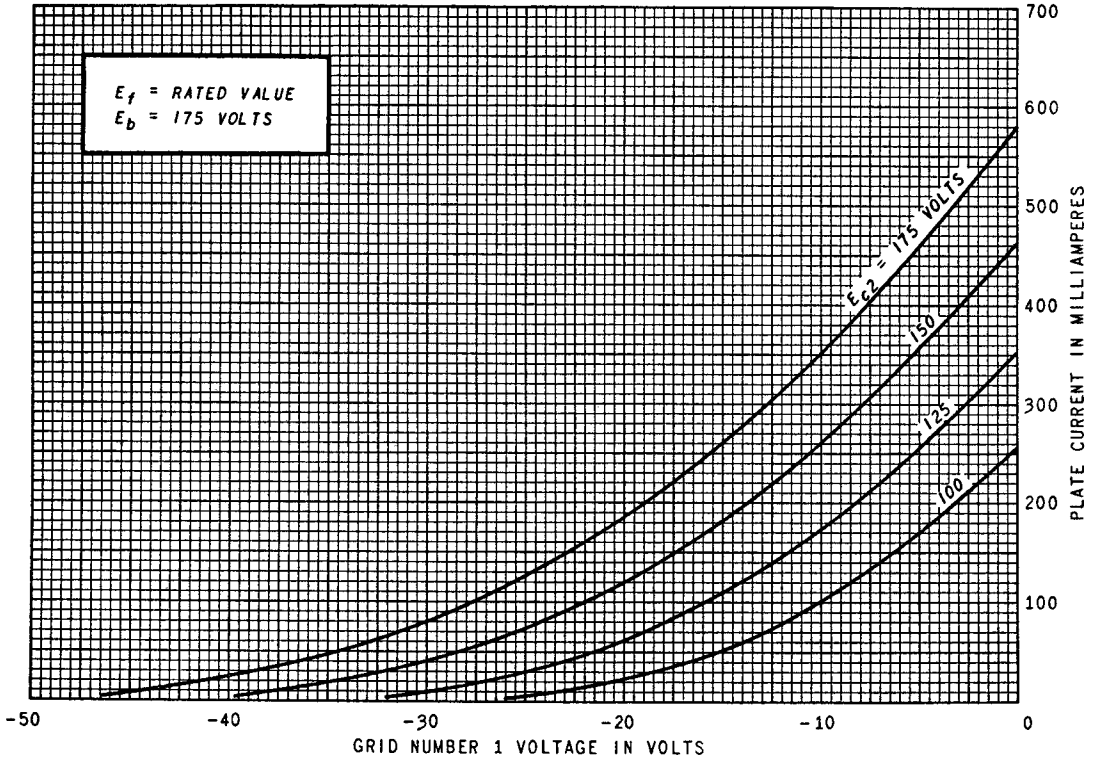
* Heater warm-up time is defined as the time required in the circuit shown at the right for the voltage across the heater terminals to increase from zero to the heater test voltage (V_1). For this type, E = 100 volts (RMS or DC), V_1 = 20.0 volts (RMS or DC), and R = 126 ohms.

† Without external shield.

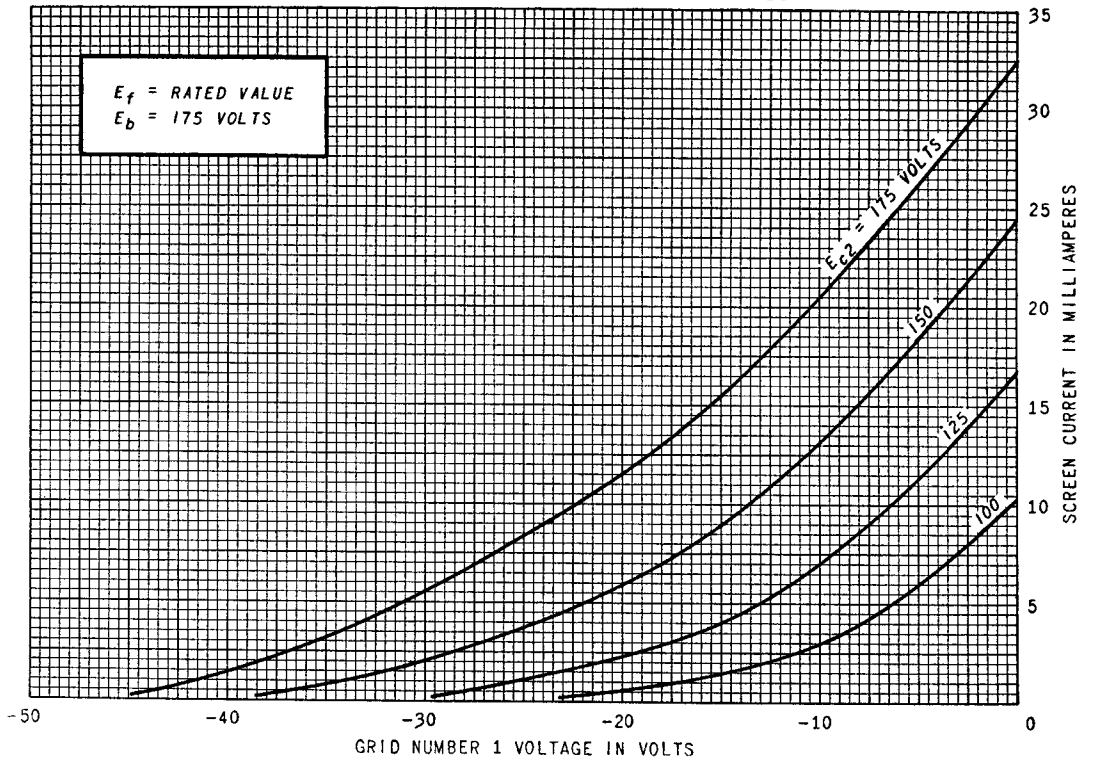
‡ Horizontal operation is permitted if pins 2 and 7 are in a vertical plane.

§ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.



▲Value given is to be considered as an Absolute Maximum Rating. In this case, the combined effect of supply voltage variation, manufacturing variation including components in the equipment, and adjustment of equipment controls should not cause the rated value to be exceeded.

π In stages operating with grid-leak bias, an adequate cathode-bias resistor or other suitable means is required to protect the tube in absence of excitation.



♦ Applied for very short interval so as not to damage tube.

Triode connection (screen tied to plate) with Eb = Ec2 = 175 volts and Ec1 = −30 volts.

Electronic TUBES

6CF6 - 3CF6

PENTODE

DESCRIPTION AND RATING

The 6CF6 is a miniature sharp-cutoff pentode designed especially for use as a gain-controlled intermediate-frequency amplifier in television receivers. Except for the plate-current cutoff characteristic, the 6CF6 is identical to the 6CB6; and like that tube features high transconductance and low interelectrode capacitances. The tube is also useful as a radio-frequency amplifier in VHF television tuners.

The 3CF6 is identical to the 6CF6 except for heater ratings. The 3CF6 in addition incorporates a controlled heater warm-up characteristic which makes it especially suited for use in television receivers that employ 600-milliampere, series-connected heaters.

Compactron Diode

6CG3

FOR TV DAMPING DIODE APPLICATIONS

- **COLOR TV TYPE**
- **LOW TUBE DROP**
- **DIFFUSION BONDED CATHODE**
- **5000 VOLTS DC**
- **350 MILLIAMPERES DC**

The 6CG3 is a compactron containing a single heater-cathode type diode. It is intended for service as the damping diode in the horizontal deflection circuit of color television receivers.

The diffusion bonded cathode practically eliminates one of the major failure mechanisms in damping diodes, which is plate-to-cathode arcing caused by emissive particles being pulled from the cathode by the high electrostatic field.

Electronic TUBES

6CG7—8CG7

TWIN TRIODE

FOR GENERAL-PURPOSE AMPLIFIER AND OSCILLATOR APPLICATIONS

DESCRIPTION AND RATING

The 6CG7 is a miniature medium-mu twin triode suitable for use in a wide variety of general-purpose applications. It is particularly useful as a vertical-deflection oscillator and horizontal-deflection oscillator in television receivers. Like the 6SN7-GTB to which it is electrically equivalent, the tube may also be used as a resistance-coupled amplifier, phase inverter, or multivibrator.

Except for heater ratings, the 8CG7 is identical to the 6CG7. Both tubes exhibit a controlled heater-warm-up characteristic which makes them especially suited for use in television receivers that employ series-connected heaters.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Diode

6CJ3

FOR TV DAMPING DIODE APPLICATIONS

- COLOR TV TYPE
- DIFFUSION BONDED CATHODE
- LOW TUBE DROP
- 5000 VOLTS DC
- 350 MILLIAMPERES DC

The 6CJ3 is a single heater-cathode type diode intended for service as the damping diode in the horizontal-deflection circuit of color television receivers. It utilizes a T-9 bulb and features a 9-pin glass button base with a 0.687-inch pin circle.

The diffusion bonded cathode practically eliminates one of the major failure mechanisms in damping diodes, which is plate-to-cathode arcing caused by emissive particles being pulled from the cathode by the high electrostatic field.

Electronic TUBE

6CL6
Description and Rating
PENTODE

The 6CL6 is a miniature power pentode designed primarily for use as the video output amplifier in television receivers. The tube exhibits high transconductance, high power sensitivity, and low interelectrode capacitances. These characteristics make the 6CL6 suitable for driving large television picture tubes at low distortion levels. The tube is also useful as a wide-band amplifier in industrial and laboratory equipment.

DESCRIPTION AND RATING

The 6CL8-A is a miniature tube which contains a sharp-cutoff tetrode and a medium-mu triode in one envelope. Primarily intended for service as a combined triode-oscillator and tetrode-mixer in VHF television tuners, the tube features a controlled heater-warm-up characteristic which makes it especially suited for use in television receivers with series-connected heaters.

The 6CL8-A is unilaterally interchangeable, both electrically and mechanically, with the 6CL8. It differs primarily from the 6CL8 in having a tetrode section with lower grid-plate capacitance and higher transconductance.

Except for heater ratings, 5CL8-A is identical with the 6CL8-A.

6CM7

DISSIMILAR DOUBLE TRIODE

FOR TV VERTICAL-DEFLECTION OSCILLATOR AND AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 6CM7 is a miniature tube which contains two dissimilar medium-mu triodes in one envelope. It is intended for use as a combined vertical-deflection oscillator and amplifier in television receivers. In this application, section one may be used as a conventional blocking oscillator, while section two is particularly adapted for vertical amplifier service as a result of its high-perveance characteristics and its 5-watt plate dissipation rating.

In addition the 6CM7 features a controlled heater warm-up characteristic which makes it especially suited for use in television receivers which employ 600-milliampere series-connected heaters.

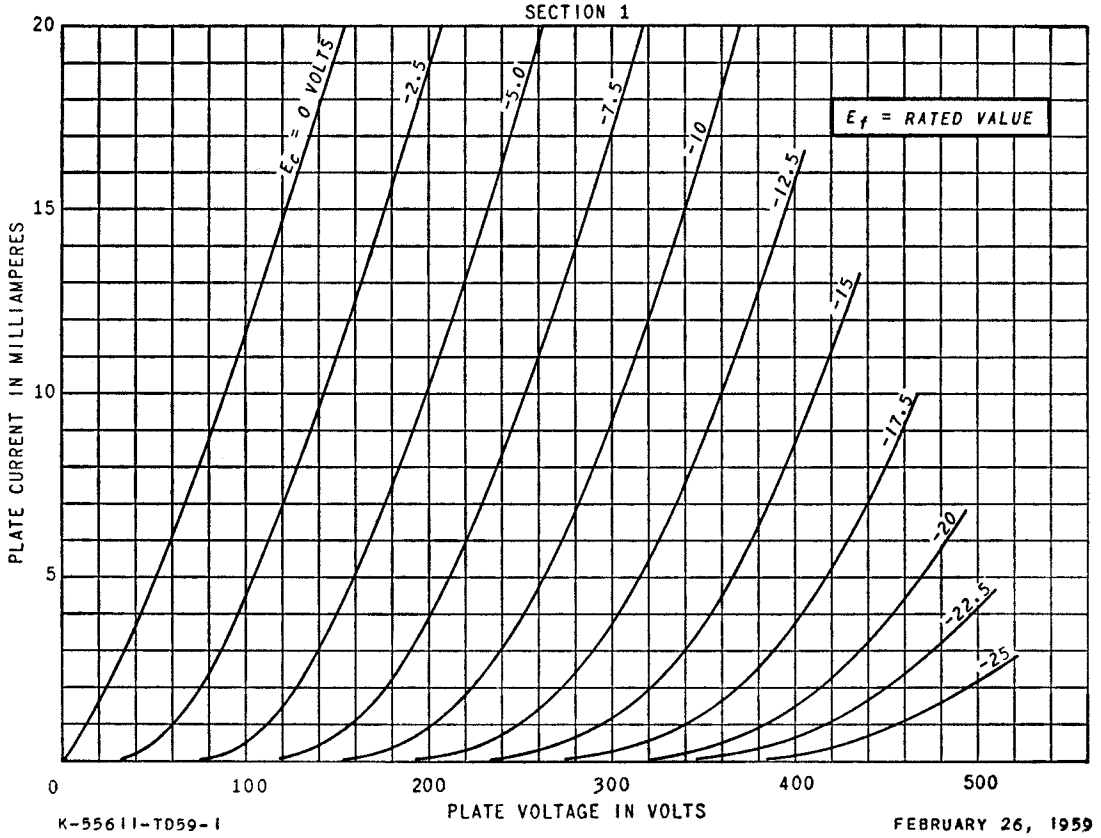
* The time required for the voltage across the heater to reach 80 percent of its rated value after applying 4 times rated heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the rated heater voltage divided by the rated heater current.

† Without external shield.

‡ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

§ Value given is to be considered as an Absolute Maximum Rating. In this case, the combined effect of supply voltage variation, manufacturing variation including components in the equipment, and adjustment of equipment controls should not cause the rated value to be exceeded.



π In stages operating with grid-leak bias, an adequate cathode-bias resistor or other suitable means is required to protect the tube in the absence of excitation.

Electronic TUBES

6CN7—8CN7

DUPLEX-DIODE TRIODE

DESCRIPTION AND RATING

The 6CN7 is a duplex-diode high-mu triode in which separate cathodes are provided for the diode and triode sections. The triode section of the 6CN7 is electrically identical to the triode section of the 6T8. The tube is primarily intended for service as a combined horizontal phase detector and reactance tube in television receivers. The triode section may also be used in a variety of other applications, such as in sync-separator, sync-amplifier, or audio-amplifier circuits.

Except for heater ratings, the 8CN7 is identical to the 6CN7. Both of the tubes incorporate a controlled heater-warm-up characteristic which makes them especially suited for use in television receivers that employ series-connected heaters.

* The time required for the voltage across the heater to reach 80 percent of its rated value after applying 4 times rated heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the rated heater voltage divided by the rated heater current.

† Without external shield.

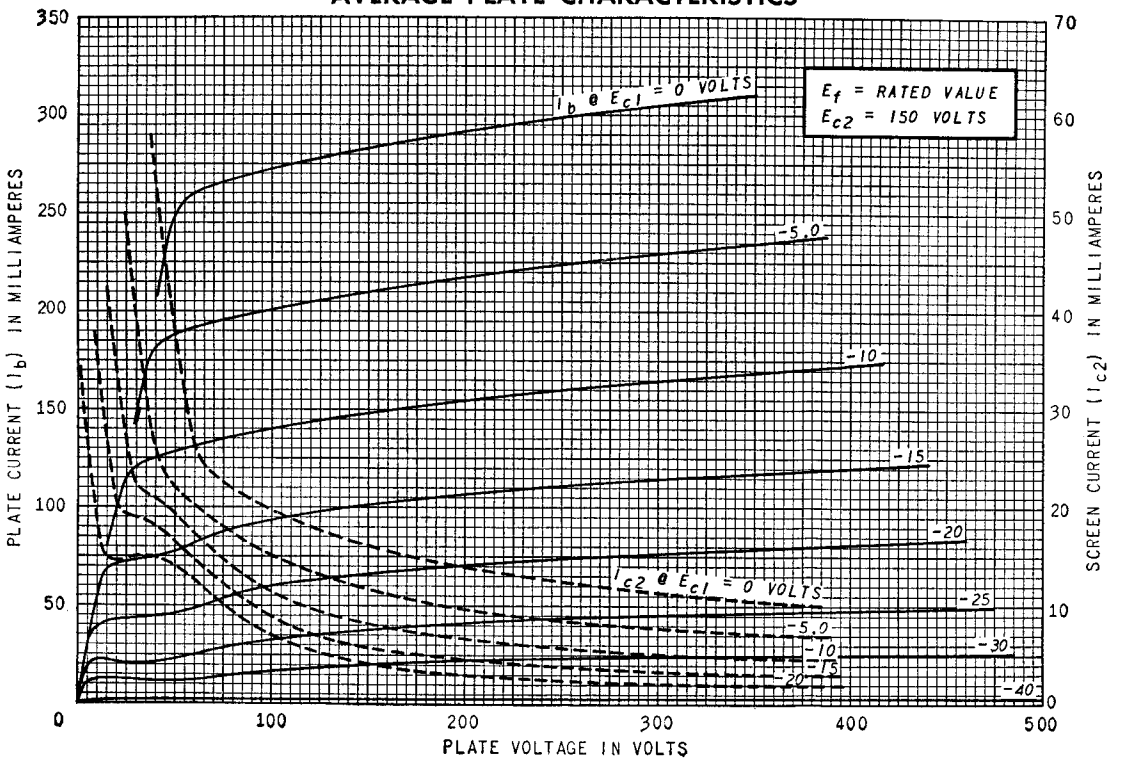
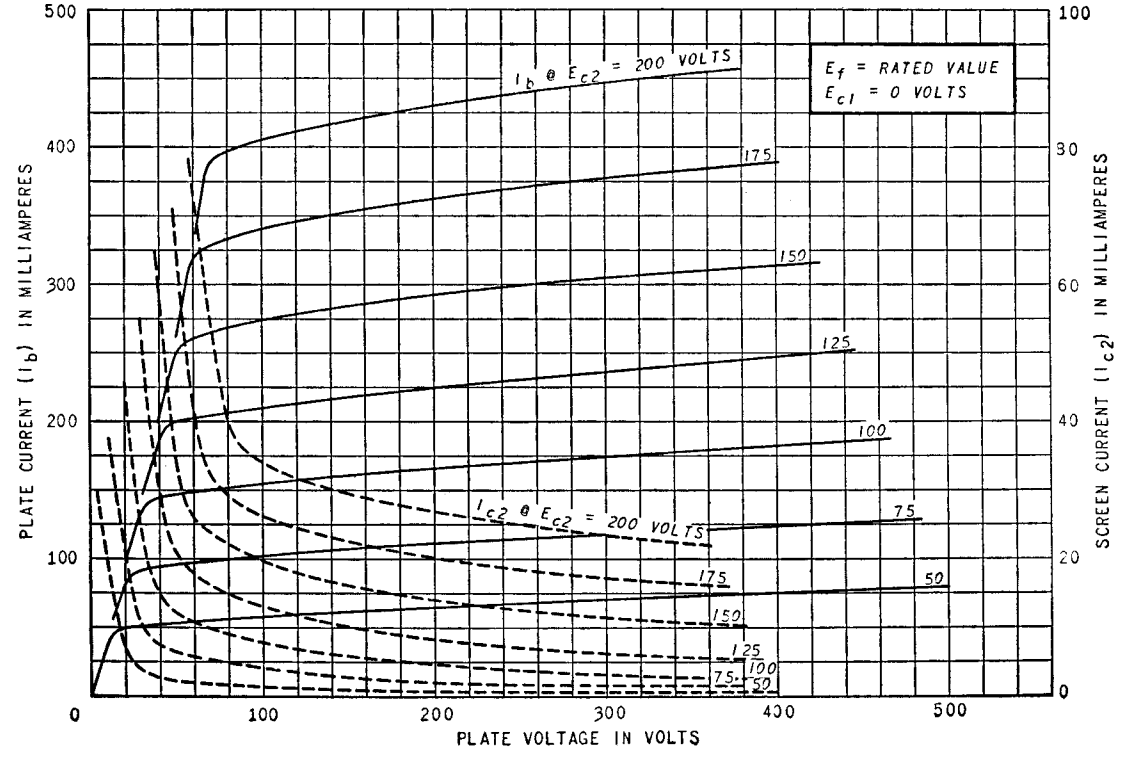
‡ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.



§ Value given is to be considered as an Absolute Maximum Rating. In this case, the combined effect of supply voltage variation, manufacturing variation including components in the equipment, and adjustment of equipment controls should not cause the rated value to be exceeded.

△In stages operating with grid-leak bias, an adequate cathode-bias resistor or other suitable means is required to protect the tube in the absence of excitation.



¶ Applied for short interval (two seconds maximum) so as not to damage tube.

**Triode connection (screen tied to plate) with $E_b = E_{c2} = 150$ volts and $E_{c1} = -22.5$ volts.

Design-Center ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under normal conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube in average applications, making allowance for normal changes in operating conditions due to rated supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially no design-center value for the intended service is exceeded with a bogey tube under normal operating conditions at the stated normal supply voltage.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

TRIODE-PENTODE

DESCRIPTION AND RATING

The 6CX8 is a miniature tube containing a sharp-cutoff pentode and a medium-mu triode in one envelope. The pentode section is intended primarily for use as a video amplifier. The triode section is suitable for a sweep oscillator, sync separator, sync amplifier, or sync clipper.

Except for heater ratings, the 8CX8 is identical to the 6CX8. In addition, it incorporates a controlled heater warm-up characteristic which makes it especially suited for use in television receivers with series-connected heaters.

6DA4—12D4—17D4

DIODE

FOR TV DAMPING DIODE APPLICATIONS

DESCRIPTION AND RATING

The 6DA4 is a single heater-cathode type diode for service as the damping diode in the horizontal-deflection circuit of television receivers. It will withstand high pulse voltages between the heater and cathode and high inverse pulse voltages between the plate and cathode. These characteristics make the tube particularly useful in autotransformer deflection systems where high pulse voltages are applied to the cathode of the damper tube.

Except for heater ratings, the 12D4 and 17D4 are identical to the 6DA4. In addition, the 12D4 and 17D4 incorporate a controlled heater-warm-up characteristic which makes them especially suited for use in television receivers with series-connected heaters.

GENERAL ELECTRIC

MAXIMUM RATINGS (Cont'd)

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

AVERAGE CHARACTERISTICS

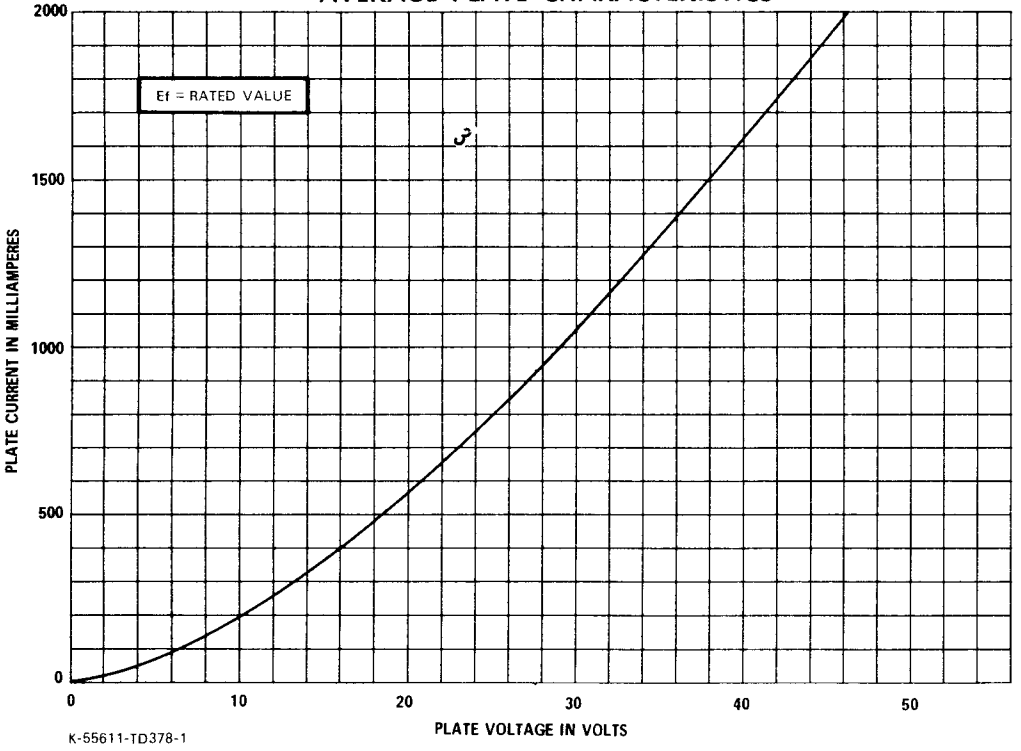
Tube Voltage Drop		
Ib = 400 Milliamperes	16	Volts
Ib = 800 Milliamperes	25	Volts

NOTES

★ The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

● Heater current of a bogey at Ef = 6.3 volts.

▲ Without external shield.



♦ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

⊕ Measured with an infrared thermometer, Ircon Model 700 BC or equivalent

§ May be used as a tie point for components at or near heater potential.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

BEAM PENTODE

FOR TV HORIZONTAL-DEFLECTION AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 6DQ6-A is a beam-power pentode primarily designed for use as the horizontal-deflection amplifier in television receivers. Its high zero-bias plate current at low plate and screen voltages makes the tube well suited for use in receivers which operate at low plate-supply voltages.

Except for heater ratings, the 12DQ6-A and 17DQ6-A are identical to the 6DQ6-A. In addition, they incorporate a controlled heater warm-up characteristic which makes them especially suited for use in television receivers that employ series-connected heaters.

6DT6 - 3DT6 - 4DT6

PENTODE

FOR FM DETECTOR APPLICATIONS

DESCRIPTION AND RATING

The 6DT6 is a miniature sharp-cutoff dual-control pentode primarily intended for use as an FM detector in television receivers. It is also suitable for use in delay circuits, gain-controlled amplifier circuits, and mixer circuits.

As an FM detector, the 6DT6 performs the combined functions of limiter and detector when used in conjunction with suitable circuitry. It also exhibits high sensitivity, and is capable of providing high audio output voltage.

Except for heater ratings, the 3DT6 and 4DT6 are identical to the 6DT6. In addition, they incorporate a controlled heater warm-up characteristic, which makes them especially suited for use in television receivers that employ series-connected heaters.

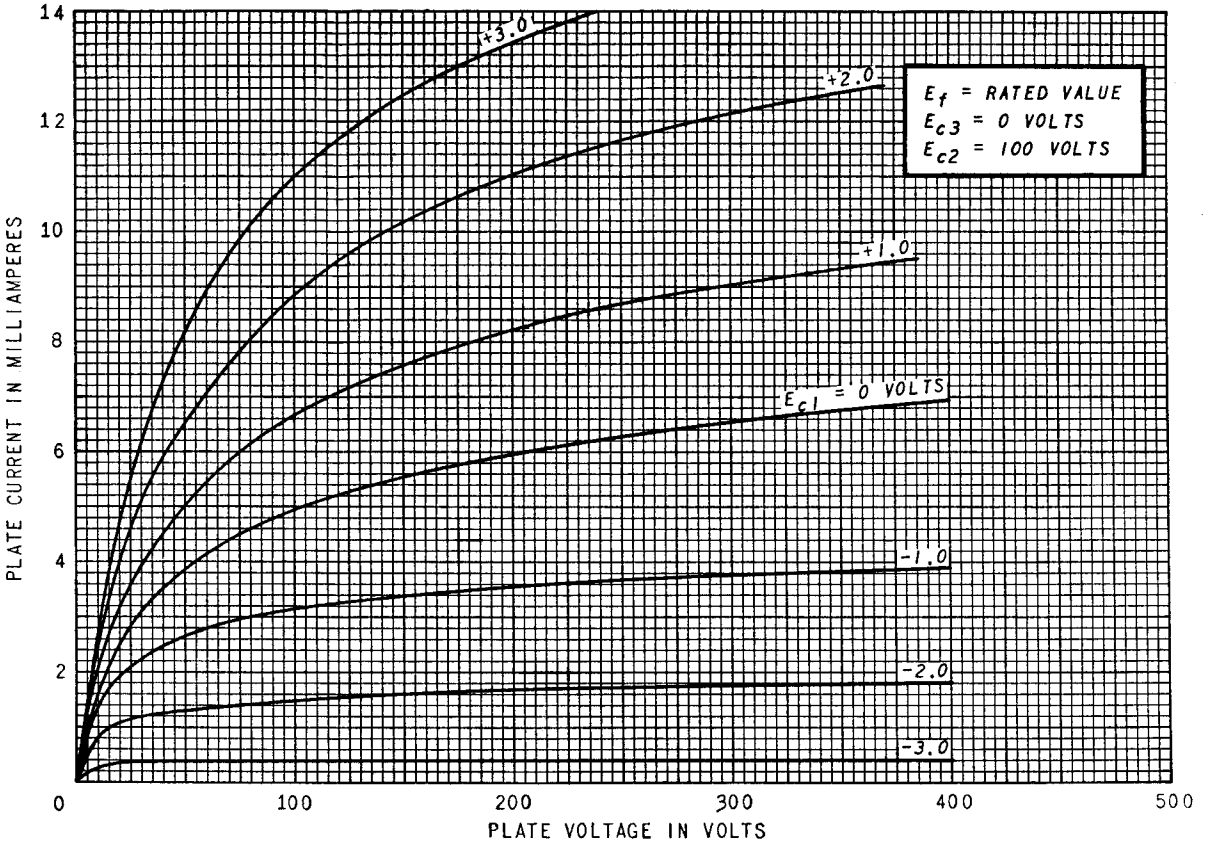
T1 - SLUG-TUNED, BIFILAR WOUND IF TRANSFORMER WITH RATIO OF 1:1.5, Q > 60, AND TUNEABLE TO 4.5-MC WITH TUBE AND WIRING CAPACITANCE



RECOMMENDED ALIGNMENT PROCEDURE

1. Feed a 500-millivolt, 4.5-mc, 400-cps FM-modulated (±25-kc deviation) signal to the input of the driver tube.
2. Adjust L1 for maximum undistorted sound output. Since several maxima may occur during this adjustment, it is important to select the proper one. This is the higher frequency peak and coincides with maximum voltage drop across R5.
3. Reduce the level of the 4.5-mc signal to 5 millivolts RMS.
4. Using an oscilloscope, adjust T1 for a centered discriminator characteristic with oscillation beats at the edges. Alternatively, T1 may be adjusted for maximum d-c voltage across R5.
5. Repeat steps 1 through 4 as necessary to assure accurate alignment.

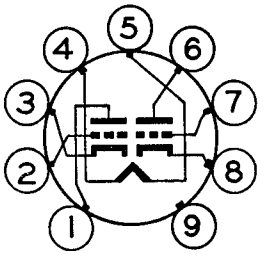
With Cathode Bias	1.0	Megohms

Design-Center ratings are limiting values of operating and environmental conditions applicable to a bogey tube of a specified type as defined by its published data, and should not be exceeded under normal conditions.



The tube manufacturer chooses these values to provide acceptable serviceability of the tube in average applications, taking responsibility for normal changes in operating conditions due to rated supply voltage variation (for an alternating-current power source, 117 volts plus or minus 10 percent is accepted USA practice), equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in tube characteristics.

The equipment manufacturer should design so that initially no design-center value for the intended service is exceeded with a bogey tube in equipment operating at the stated normal supply voltage.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

6EA8

TRIODE-PENTODE
FOR VHF CONVERTER APPLICATIONS

DESCRIPTION AND RATING

The 6EA8 is a miniature tube which contains a sharp-cutoff pentode and a triode in one envelope. Each section has a separate cathode and is electrically independent. The tube is primarily intended for service as a combined triode oscillator and pentode mixer in television receivers. Incorporation of a controlled heater warm-up characteristic makes the tube especially suited for use in television receivers that employ series-connected heaters.

SCREEN RATING CHART

Compactron Beam Triode

6EH4-A

FOR HV SHUNT REGULATOR APPLICATIONS

■ COLOR TV TYPE ■ 27000 VOLTS DC ■ 40 WATTS PLATE DISSIPATION ■ X-RADIATION RATING

The 6EH4-A is a low-current, high-voltage, beam triode intended for use as a shunt regulator in the high-voltage power supply of color television receivers.

The 6EH4-A has a maximum d-c plate-voltage rating of 27000 volts, a maximum d-c plate current rating of 1.5 milliamperes, and a maximum plate-dissipation rating of 40 watts.

Features of the 6EH4-A include built-in X-radiation shielding and additional design and specification controls for the reduction of X-radiation output. The 6EH4-A also features the utilization of a high voltage shield to minimize the effects of a momentary arc within the tube.

MAXIMUM RATINGS (Cont'd)

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

CHARACTERISTICS AND TYPICAL OPERATION

AVERAGE CHARACTERISTICS

Unregulated DC Supply Voltage	36000	Volts
Equivalent Resistance of Unregulated Supply	11	Megohms
DC Reference Voltage	200	Volts
Equivalent Resistance of Reference Supply	1000	Ohms
Effective Grid-Plate Transconductance	200	Micromhos
DC Plate Current for Zero Load Current	1000	Microamperes
DC Plate Current for Load Current of 1 Milliampere	45	Microamperes
Regulated DC Output Voltage at Zero Load Current	25000	Volts
Regulated DC Output Voltage at Load Current of 1 Milliampere	24500	Volts

X-RADIATION RATING

X-radiation, maximum	0.5	mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 0.5 mR/hr at any time throughout their useful life, when operated within the maximum ratings, including heater voltage, specified on this data sheet.

This X-radiation maximum rating is based on the use of the Victoreen 440 RF/C survey meter as the standard instrument for X-radiation measurement. X-radiation is measured with the plastic spacer of the 440 RF/C survey meter at a distance of four (4) inches from the external surface of the tube under test. This rating information is not necessarily applicable when a different radiation measuring instrument is used.

Operation of the 6EH4-A outside of the Absolute-Maximum Ratings indicated may damage the tube and/or result in either temporary or permanent changes in the X-radiation characteristics of the tube. Equipment design must be such that these Absolute-Maximum Ratings are not exceeded.

The above X-radiation characteristics are measured in accordance with JEDEC Publication No. 67A, "Recommended Practice for Measurement of X-radiation form Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73A, "Recommended Practice for Quality Control of X-radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

WARNING

X-RADIATION

Operation of the 6EH4-A outside of the Absolute-Maximum Ratings indicated may produce soft X-rays above 0.5 milliroentgens per hour which may constitute a health hazard on prolonged exposure at close range unless the tube is adequately shielded. Equipment design must provide required shielding.

Precautions must be exercised during the servicing of the equipment employing the 6EH4-A to assure that the high voltage is adjusted to the recommended value ano that any shielding components are replaced to their intended positions before the equipment is operated.

SHOCK HAZARD

The high voltages at which the 6EH4-A is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and for the servicing and adjustment of any high voltage circuit.

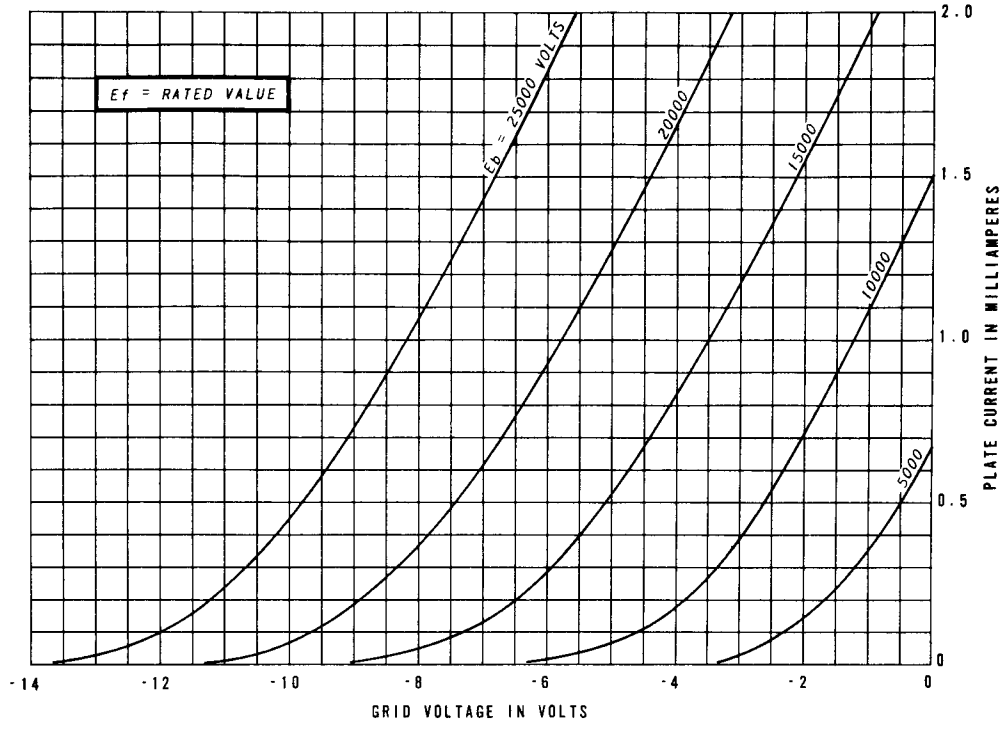
Precautions must be exercised during the replacement or servicing of the 6EH4-A in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN.

NOTES

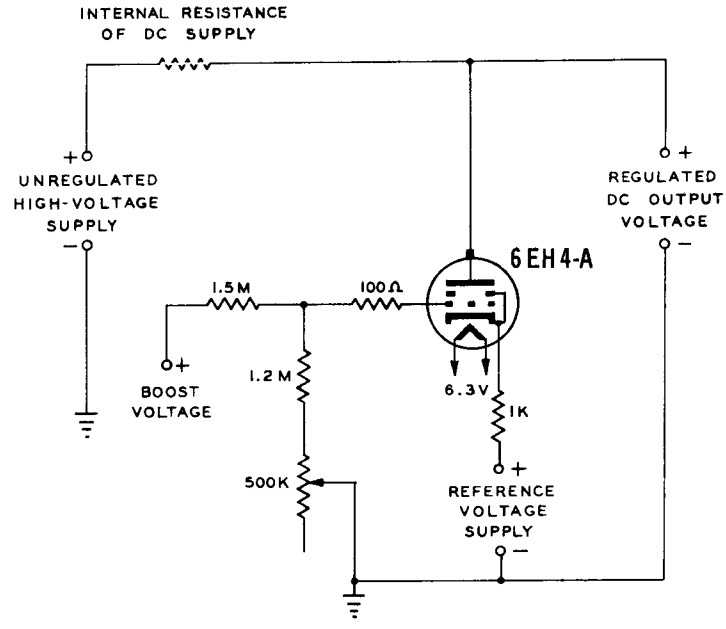
* The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

● Heater current of a bogey tube at Ef = 6.3 volts.



▲ Without external shield.

♦ Peak value for duration of 20 seconds maximum during equipment warmup.



§ Sufficient impedance (1000 ohms is recommended) should be in series with the cathode to limit the cathode current under prolonged heater-cathode short-circuit conditions to 450 ma. This protective impedance will minimize the danger of heater burnout in case of a momentary heater-cathode arc within the tube.

⊕ With flyback transformer high-voltage supply.

AVERAGE TRANSFER CHARACTERISTICS

TYPICAL SHUNT REGULATOR CIRCUIT

APPLICATION CONSIDERATIONS

The base pins of the 6EH4-A fit the standard compactron socket. Socket terminals for pins 2, 3, 4, 8, 9, 10 and 11 should not be used for tie points. Tube performance may be adversely affected should this precaution not be followed.

Sufficient impedance (1000 ohms is suggested) should be in series with the cathode to limit the cathode current under prolonged heater-cathode short circuit conditions to 450 ma. This protection impedance will minimize the danger of heater burnout in case of a momentary heater-cathode arc within the tube.

A unique design feature of the 6EH4-A is the utilization of a high voltage shield to minimize the effects of a momentary arc within the tube. This shield is brought out to a separate pin so that it can be tied directly to ground, whereas it has been customary in the more conventional tubes of this type to tie the shield directly to the cathode. When the shield is tied to the cathode, any arcing can cause failure of the cathode-resistor and/or breakdown of the heater cathode insulation, failures which the 6EH4-A has been designed to prevent.

The high voltages at which the 6EH4-A is operated may be very hazardous. Extreme caution should be used while making any circuit adjustments. The 6EH4-A and all of its associated hardware should be housed in a protective enclosure. It is particularly important that all parts which may be at a high potential with respect to ground be housed in this protective enclosure. The protective enclosure should be constructed with a system of interlocks to prevent anyone from coming in contact with any high potential point in the electrical system. The interlocks should break the primary circuit of the high-voltage supply when any part of the protective enclosure is open, and should prevent the closing of the primary circuit until the protective enclosure is closed and locked.

High voltages may appear at points in the circuit which are normally at low potentials as a result of improper circuit connection or of capacitor breakdown. Therefore, before touching any part of the circuit, the power supply switch should be turned off and both terminals of any capacitor should be grounded.

The bulb of the 6EH4-A becomes hot during operation. Therefore, it is essential that provision be made for free circulation of air around the tube in order to insure sufficient cooling.

The plate of the 6EH4-A exhibits a dull red color when the tube is operated at maximum plate dissipation. In addition it may exhibit a bluish glow on the upper half of the bulb inner wall surface during normal operation. This bluish glow is a result of fluorescence and it should not be mistaken for gas.

To prevent any strain from being exerted on the seal of the plate cap, it is important that connection to the plate cap be made by an appropriate connector which has a flexible lead.

6EH8

TRIODE-PENTODE

FOR VHF CONVERTER APPLICATIONS

DESCRIPTION AND RATING

The 6EH8 is a miniature tube which contains a sharp-cutoff pentode and a triode in one envelope. It is intended primarily for use as a combined triode oscillator and pentode mixer in television receivers. The 6EH8 incorporates a controlled heater-warm-up characteristic.

Compactron Beam Triode

6EJ4-A

FOR HV SHUNT REGULATOR APPLICATIONS

■ COLOR TV TYPE ■ 27000 VOLTS DC ■ 40 WATTS PLATE DISSIPATION ■ X-RADIATION RATING

The 6EJ4-A is a low-current, high-voltage, beam triode intended for use as a shunt regulator in the high-voltage power supply of color television receivers.

The 6EJ4-A has a maximum d-c plate-voltage rating of 27000 volts, a maximum d-c plate current rating of 1.5 milliamperes, and a maximum plate-dissipation rating of 40 watts.

Features of the 6EJ4-A include built-in X-radiation shielding and additional design and specification controls for the reduction of X-radiation output. The 6EJ4-A also features the utilization of a high voltage shield to minimize the effects of a momentary arc within the tube.

X-RADIATION RATING

X-radiation, maximum	0.5	mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 0.5 mR/hr at any time throughout their useful life, when operated within the maximum ratings, including heater voltage, specified on this data sheet.

This X-radiation maximum rating is based on the use of the Victoreen 440 RF/C survey meter as the standard instrument for X-radiation measurement. X-radiation is measured with the plastic spacer of the 440 RF/C survey meter at a distance of four (4) inches from the external surface of the tube under test. This rating information is not necessarily applicable when a different radiation measuring instrument is used.

Operation of the 6EJ4-A outside of the Absolute-Maximum Ratings indicated may damage the tube and/or result in either temporary or permanent changes in the X-radiation characteristics of the tube. Equipment design must be such that these Absolute-Maximum Ratings are not exceeded.

The above X-radiation characteristics are measured in accordance with JEDEC Publication No. 67A, "Recommended Practice for Measurement of X-radiation form Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73A, "Recommended Practice for Quality Control of X-radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

WARNING

X-RADIATION

Operation of the 6EJ4-A outside of the Absolute-Maximum Ratings indicated may produce soft X-rays above 0.5 milliroentgens per hour which may constitute a health hazard on prolonged exposure at close range unless the tube is adequately shielded. Equipment design must provide required shielding.

Precautions must be exercised during the servicing of the equipment employing the 6EJ4-A to assure that the high voltage is adjusted to the recommended value and that any shielding components are replaced to their intended positions before the equipment is operated.

SHOCK HAZARD

The high voltages at which the 6EJ4-A is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and for the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 6EJ4-A in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

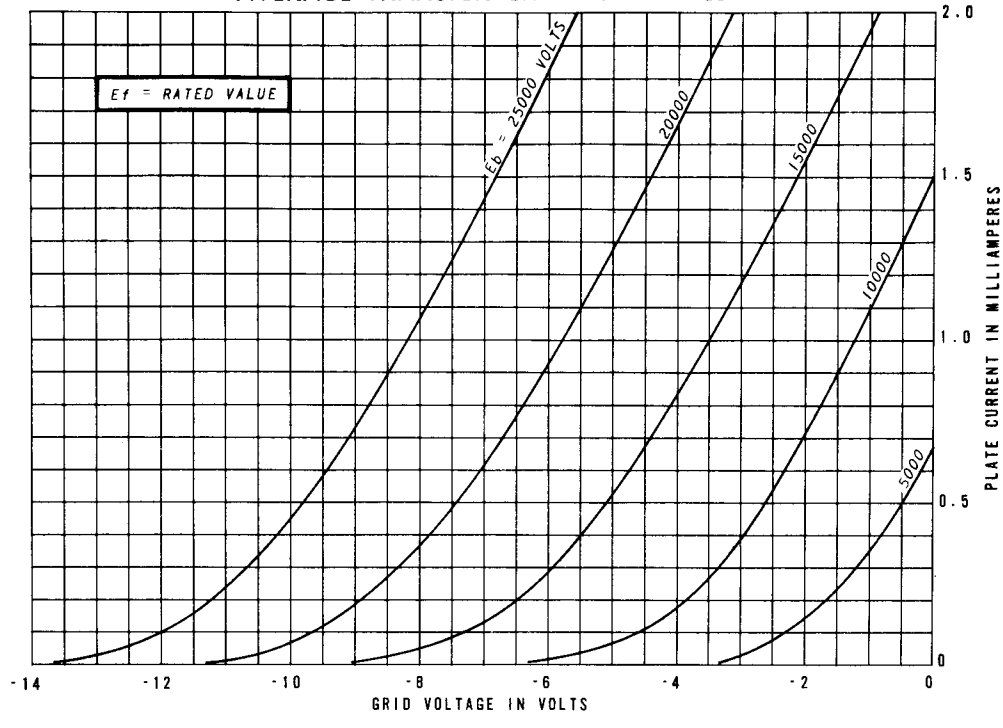
THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN.

NOTES

★ The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

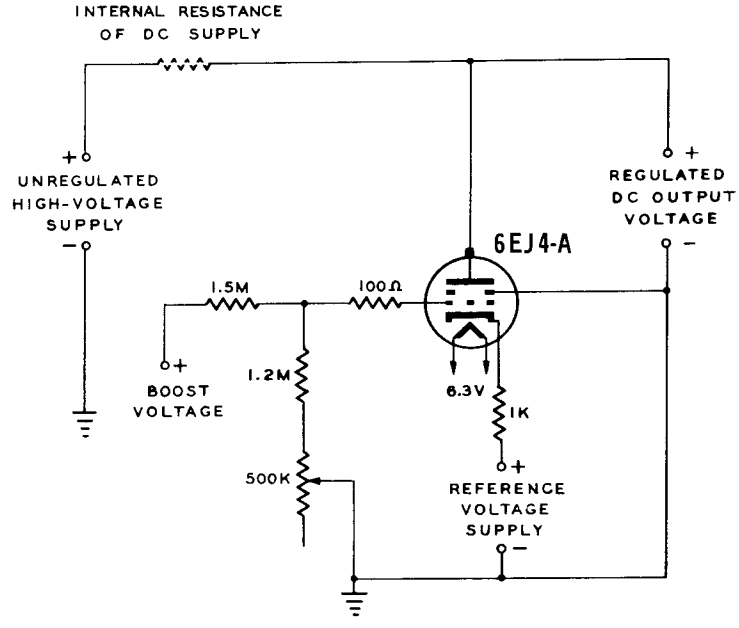
● Heater current of a bogey tube at Ef = 6.3 volts.

▲ Without external shield.



♦ Peak value for duration of 20 seconds maximum during equipment warmup.

§ Sufficient impedance (1000 ohms is recommended) should be in series with the cathode to limit the cathode current under prolonged heater-cathode short-circuit conditions to 450 ma. This protective impedance will minimize the danger of heater burnout in case of a momentary heater-cathode arc within the tube.



⊕ With flyback transformer high-voltage supply.

APPLICATION CONSIDERATIONS

The base pins of the 6EL4-A fit the standard octal socket. Socket terminals for pins 3, 4, and 8 should not be used for tie points. Tube performance may be adversely affected should this precaution not be followed.

Sufficient impedance (1000 ohms is suggested) should be in series with the cathode to limit the cathode current under prolonged heater-cathode short circuit conditions to 450 ma. This protection impedance will minimize the danger of heater burnout in case of a momentary heater-cathode arc within the tube.

The high voltages at which the 6EL4-A is operated may be very hazardous. Extreme caution should be used while making any circuit adjustments. The 6EL4-A and all of its associated hardware should be housed in a protective enclosure. It is particularly important that all parts which may be at a high potential with respect to ground be housed in this protective enclosure. The protective enclosure should be constructed with a system of interlocks to prevent anyone from coming in contact with any high potential point in the electrical system. The interlocks should break the primary circuit of the high-voltage supply when any part of the protective enclosure is open, and should prevent the closing of the primary circuit until the protective enclosure is closed and locked.

High voltages may appear at points in the circuit which are normally at low potentials as a result of improper circuit connection or of capacitor breakdown. Therefore, before touching any part of the circuit, the power supply switch should be turned off and both terminals of any capacitor should be grounded.

The bulb of the 6EL4-A becomes hot during operation. Therefore, it is essential that provision be made for free circulation of air around the tube in order to insure sufficient cooling.

The plate of the 6EL4-A exhibits a dull red color when the tube is operated at maximum plate dissipation. In addition, it may exhibit a bluish glow on the upper half of the bulb inner wall surface during normal operation. This bluish glow is a result of fluorescence and it should not be mistaken for gas.

To prevent any strain from being exerted on the seal of the plate cap, it is important that connection to the plate cap be made by an appropriate connector which has a flexible lead.

GENERAL ELECTRIC

—PRODUCT INFORMATION—

Beam Triode

6EN4

FOR HV SHUNT REGULATOR APPLICATIONS

■ COLOR TV TYPE ■ 30000 VOLTS DC ■ 40 WATTS PLATE DISSIPATION ■ X-RADIATION RATING

The 6EN4 is a low current, high-voltage, sharp cutoff beam triode intended for use as a shunt regulator in the high-voltage power supply of color television receivers.

The 6EN4 has a maximum d-c plate voltage rating of 30000 volts, a maximum d-c plate current rating of 1.6 milli-amperes, and a maximum plate-dissipation rating of 40 watts.

The basing of the 6EN4 has been designed to permit the original equipment manufacturer to wire the tube socket so as to prevent the earlier high voltage regulator tubes from being used in place of the 6EN4. Moreover, the 6EN4, with its improved X-radiation features, can be used as a replacement for the 6BK4, 6BK4-A, 6BK4-C and 6EL4-A in earlier color television receivers.

Features of the 6EN4 include built-in X-radiation shielding and additional design and specification controls for the reduction of X-radiation output.

GENERAL ELECTRIC

MAXIMUM RATINGS (Cont'd)

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

CHARACTERISTICS AND TYPICAL OPERATION

AVERAGE CHARACTERISTICS

Unregulated DC Supply Voltage	36000	Volts
Equivalent Resistance of Unregulated Supply	11	Megohms
Voltage Divider Values:		
R1 (5 Watts)	220	Megohms
R2 (2 Watts)	1	Megohms
R3 (½ Watt)	0.82	Megohms
DC Reference Voltage	200	Volts
Equivalent Resistance of Reference Supply	1000	Ohms
Effective Grid-Plate Transconductance	200	Micromhos
DC Plate Current for Zero Load Current	1000	Microamperes
DC Plate Current for Load Current of 1 Milliampere	45	Microamperes
Regulated DC Output Voltage at Zero Load Current	25000	Volts
Regulated DC Output Voltage at Load Current of 1 Milliampere	24500	Volts

X-RADIATION RATING

X-radiation, maximum	0.5	mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 0.5 mR/hr at any time throughout their useful life, when operated within the maximum ratings, including filament voltage, specified on this data sheet.

This X-radiation maximum rating is based on the use of the Victoreen 440 RF/C survey meter as the standard instrument for X-radiation measurement. X-radiation is measured with the plastic spacer of the 440 RF/C survey meter at a distance of four (4) inches from the external surface of the tube under test. This rating information is not necessarily applicable when a different radiation measuring instrument is used.

Operation of the 6EN4 outside of the Absolute-Maximum Ratings indicated may damage the tube and/or result in either temporary or permanent changes in the X-radiation characteristics of the tube. Equipment design must be such that these Absolute-Maximum Ratings are not exceeded.

The above X-radiation characteristics are measured in accordance with JEDEC Publication No. 67A, "Recommended Practice for Measurement of X-radiation from Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73A, "Recommended Practice for Quality Control of X-radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein.

WARNING

X-RADIATION

Operation of the 6EN4 outside of the Absolute-Maximum Ratings indicated may produce soft X-rays above 0.5 milliroentgens per hour which may constitute a health hazard on prolonged exposure at close range unless the tube is adequately shielded. Equipment design must provide required shielding.

Precautions must be exercised during the servicing of the equipment employing the 6EN4 to assure that the high voltage is adjusted to the recommended value and that any shielding components are replaced to their intended positions before the equipment is operated.

SHOCK HAZARD

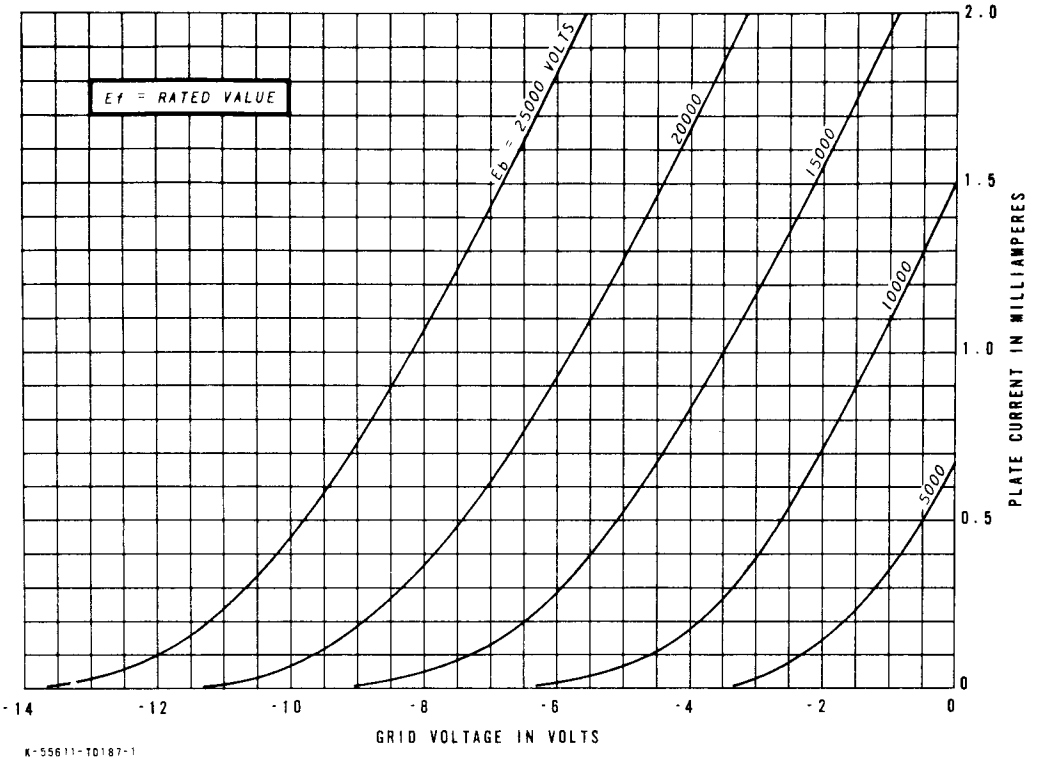
The high voltages at which the 6EN4 is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and for the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 6EN4 in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN.

NOTES

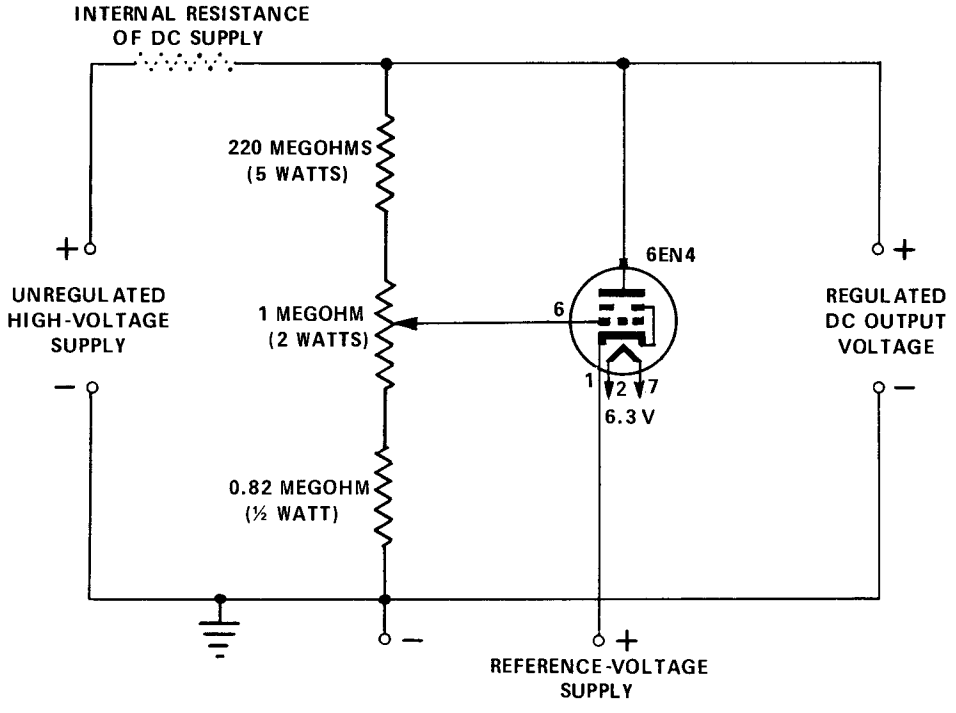
* The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.



● Heater current of a bogey at Ef = 6.3 volts.

▲ Without external shield.

♦ Peak value for duration of 20 seconds maximum during equipment warmup.



§ Sufficient impedance (1000 ohms is recommended) should be in series with the cathode to limit the cathode current under prolonged heater-cathode short-circuit conditions to 450 ma. This protective impedance will minimize the danger of heater burnout in case of a momentary heater-cathode arc within the tube.

AVERAGE TRANSFER CHARACTERISTICS

K-55611-T0187-1

TYPICAL SHUNT REGULATOR CIRCUIT

APPLICATION CONSIDERATIONS

The base pins of the 6EN4 fit the standard octal socket. Socket terminals for pins 3, 4, and 8 should not be used for tie points. Tube performance may be adversely affected should this precaution not be followed.

Sufficient impedance (1000 ohms is suggested) should be in series with the cathode to limit the cathode current under prolonged heater-cathode short circuit conditions to 450 ma. This protection impedance will minimize the danger of heater burnout in case of a momentary heater-cathode arc within the tube.

The bulb of the 6EN4 becomes hot during operation. Therefore, it is essential that provision be made for free circulation of air around the tube in order to insure sufficient cooling. Darkening of the bulb during service is a normal occurrence and has no effect on performance of the 6EN4.

The plate of the 6EN4 exhibits a dull red color when the tube is operated at maximum plate dissipation. In addition, it may exhibit a bluish glow on the upper half of the bulb inner wall surface during normal operation. This bluish glow is a result of fluorescence and it should not be mistaken for gas.

To prevent any strain from being exerted on the seal of the plate cap, it is important that connection to the plate cap be made by an appropriate connector which has a flexible lead.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey tube of a specified type as defined by its published data, and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, taking responsibility for the effects of changes in operating conditions due to variations in tube characteristics.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, and environmental conditions.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

6FG5

"SHADOW-GRID" BEAM PENTODE

FOR VHF RF AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 6FG5 is a miniature tube, similar in construction to a beam pentode, with an internally connected grid between the control grid and the screen grid which serves to reduce the ratio of screen current to plate current. The tube is designed for use as a radio-frequency amplifier in VHF television receivers.

TRIODE—PENTODE

For VHF Converter Applications

DESCRIPTION AND RATING

The 6FG7 is a miniature tube that contains a medium-mu triode and a sharp-cutoff pentode in one envelope. Primarily designed for use as a combined triode oscillator and pentode mixer in VHF television receivers, the tube features two cathode leads connected to separate base pins to reduce the effective cathode lead inductance.

Except for heater ratings, the 5FG7 is identical to the 6FG7.

MAXIMUM RATINGS

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

6FS5

"SHADOW-GRID" BEAM PENTODE

DESCRIPTION AND RATING

FOR VHF RF AMPLIFIER APPLICATIONS

The 6FS5 is a miniature tube, similar in construction to a beam pentode, with an internally connected grid between the control grid and the screen grid, which serves to reduce the ratio of screen current to plate current. The tube is designed for use as a radio-frequency amplifier in VHF television receivers.

Bulb Temperature at Hottest Point	200	C

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

CHARACTERISTICS AND TYPICAL OPERATION

Dissimilar Double Triode

6GF7-A

FOR TV VERTICAL-DEFLECTION OSCILLATOR AND AMPLIFIER APPLICATIONS

■ COLOR TV TYPE ■ T-9 ENVELOPE ■ DISSIMILAR DOUBLE TRIODE

The 6GF7-A is a dissimilar double triode designed for use as a combined vertical-deflection oscillator and amplifier in television receivers. Section one, a high-mu triode, is intended for service as an oscillator; section two, a low-mu, high-perveance triode, for service as an amplifier.

The 6GF7-A utilizes a T-9 bulb and features a 9-pin glass button base with a 0.687-inch circle.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

MAXIMUM RATINGS (Cont'd)

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

CHARACTERISTICS AND TYPICAL OPERATION

MAXIMUM RATINGS

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

NOTES

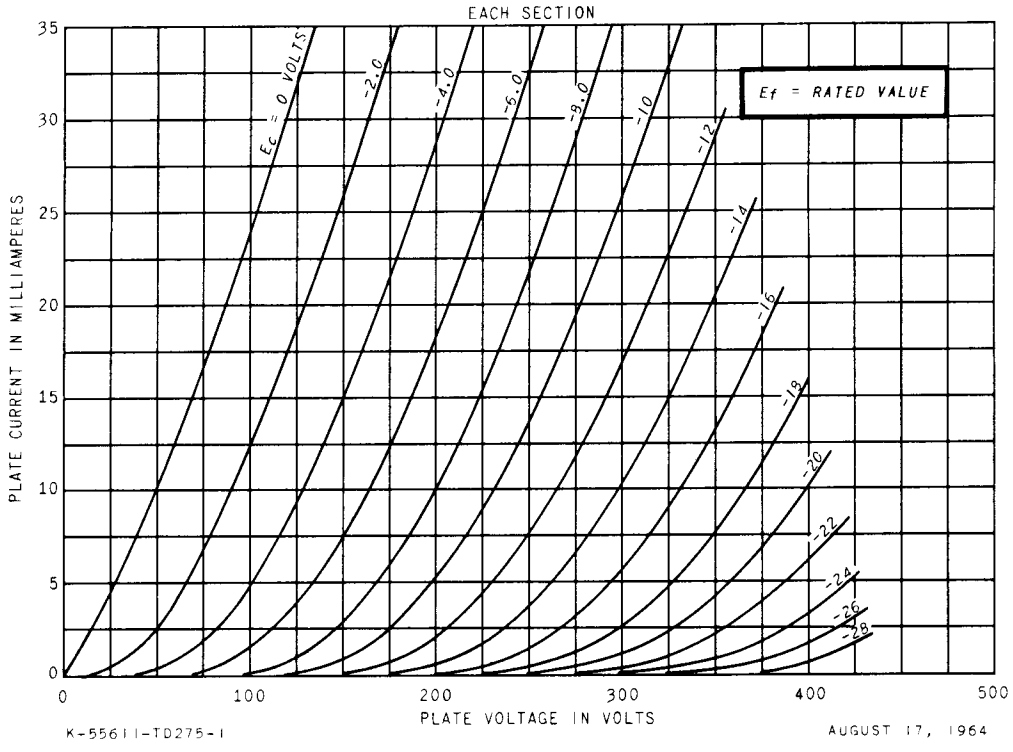
* Operated with the heater in series with the heaters of other tubes having the same bogey heater current.

‡ Operated with the heater in parallel with the heaters of other tubes having the same bogey heater voltage.

§ For parallel heater operation, the equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance; for series heater operation, the equipment designer should design the equipment so that heater current is centered at the specified bogey value, with heater supply variations restricted to maintain heater current within the specified tolerance.



¶ Heater current of a bogey tube at Ef = 6.3 volts.

The time required for the voltage across the heater to reach 80 percent of the bogey value after applying 4 times the bogey heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the bogey heater voltage divided by the bogey heater current.

Δ Without external shield.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

MAXIMUM RATINGS

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Compactron Beam Triode

6HV5-A

- COLOR TV TYPE
- FRAME-GRID CONSTRUCTION
- DIFFUSION BONDED CATHODE
- 35 WATTS PLATE DISSIPATION
- 325 MILLIAMPERES PEAK PLATE CURRENT
- TRANSCONDUCTANCE = 65000 MICROMHOS

The 6HV5-A is a compactron frame-grid beam triode suited for use as a pulse-type high-voltage regulator in the high-voltage power supply of color television receivers.

Features of the 6HV5-A include a diffusion bonded cathode coating which provides a positive bond between the cathode coating and base material, thereby practically eliminating grid-to-cathode shorts caused by cathode flaking. By operating at a relatively low potential (3500 volts), this pulse-type regulator provides much less stress on internal components than shunt regulators operating in the 25000-volt range.

NOTES

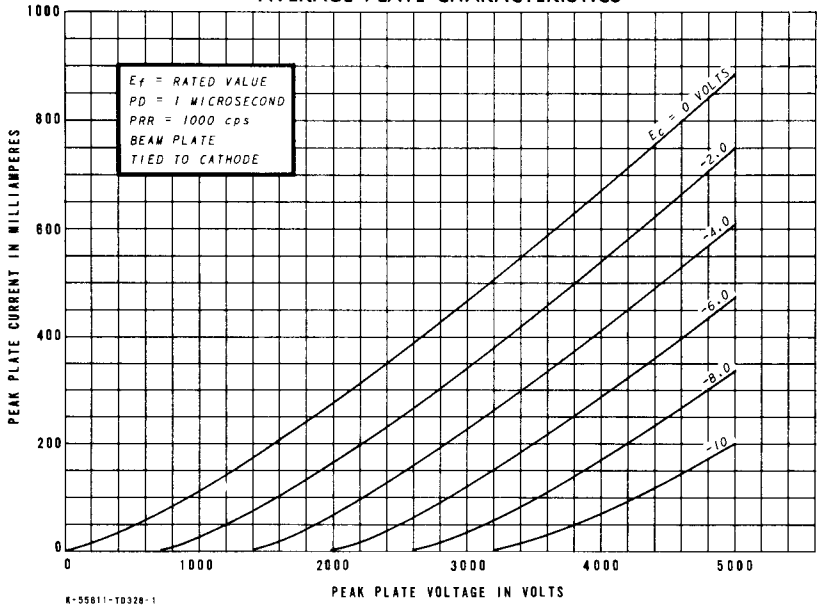
★ The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

● Heater current of a bogey tube at Ef = 6.3 volts.

♦ Without external shield.

§ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations", Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

⊕ Sufficient impedance (220 ohms by-passed with a 0.01 microfarad capacitor is suggested) should be in series with the cathode to limit the cathode current under prolonged heater-cathode short-circuit conditions. This protective impedance will minimize the danger of heater burnout in case of a momentary heater-cathode arc within the tube.



▲ Larger values of grid-circuit resistance may be used if provisions are made to protect the tube.

□ Duty cycle of the pulse must be less than 2.5 percent.

† Measured with an infrared thermometer, Ircon Model 700 BC or equivalent, at an ambient temperature of 40° C.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

6HW8

SHEET-BEAM TUBE

The 6HW8 is a miniature, double-plate, sheet-beam tube which incorporates a pair of balanced deflectors to direct the electron beam to either of the two plates, and a control grid to vary the intensity of the beam.

Grid-Number 1 Circuit Resistance		
With Cathode Bias	0.25	Megohms

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operation conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Deflector-Number 2 Current, maximum Ed1 = +38 Volts, Ed2 = +2 Volts Eb = 225 Volts, Eg1 = +3 Volts	55	Microamperes

* The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

\+ Heater current of a bogey tube at Ef = 6.3 volts.

‡ Without external shield.

\# Deflector switching voltage is defined as the total voltage change on either deflector with an equal and opposite change on the other deflector required to switch the plate current from one plate to the other.

TRIODE-PENTODE

DESCRIPTION AND RATING

The 6HZ8 is a 9-pin, T-9 tube containing a high-mu triode and a sharp-cutoff pentode. The triode is intended for use as a voltage amplifier or sync separator, and the pentode is intended for video amplifier service.

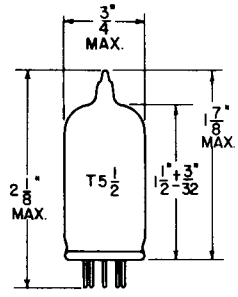
6J4

Description and Rating

HIGH-FREQUENCY TRIODE

GENERAL DESCRIPTION



Principal Application: The 6J4 is a miniature high-mu triode designed for use as a grounded-grid amplifier at frequencies up to approximately 500 megacycles. The tube features an extremely high transconductance of 12000 micromhos and permits operation with a high signal-to-noise ratio. Three terminals on the grid provide effective grounding with a minimum of reactance. The 6J4 may also be used in conventional triode circuits with an ungrounded grid.

TWIN TRIODE

DESCRIPTION AND RATING

The 6J6 is a miniature medium-mu twin triode designed for use as a radio-frequency amplifier, oscillator, or mixer. With the grids connected in push-pull and the plates connected in parallel, each type may be used as a mixer at frequencies as high as 600 megacycles.

The 5J6, 6J6, and 19J6 are alike except for heater ratings and heater-cathode ratings. The 5J6, in addition, exhibits a controlled heater warm-up characteristic which makes the tube especially suited for use in television receivers which employ series-connected heaters. When the 5J6 is used in conjunction with other 600-milliampere types which exhibit essentially the same heater warm-up characteristic, heater voltage surges across the individual tubes are minimized during the warm-up period.

* Heater warm-up time is defined as the time required in the circuit shown at the right for the voltage across the heater terminals to increase from zero to the heater test voltage (V_1). For this type, E = 18.7 volts (RMS or DC), V_1 = 3.73 volts (RMS or DC), and R = 23.5 ohms.

† With external shield (RETMA 316) connected to pin 7.
‡ Operation with fixed bias is not recommended.
§ Each section separately with specified voltages applied to both sections.
π Obtained by a 625-ohm grid resistor, a 220-ohm cathode resistor, or a fixed-voltage supply.
△Each section separately with grid and plate of opposite section grounded. In actual service, the value of the cathode-bias resistor is determined by the total cathode current of both sections.
Note: Approximately 1.0 watt can be obtained when the tube is operated as a push-pull oscillator at 250 megacycles with a plate voltage of 150 volts, with maximum rated plate dissipation, and with a grid resistor of 2000 ohms common to both sections.

6JB5

FOR TV VERTICAL-DEFLECTION AMPLIFIER APPLICATIONS

- COLOR TV TYPE
- 15 WATTS PLATE DISSIPATION
- VERTICAL OUTPUT TYPE
- HIGH VOLTAGE SCREEN GRID
- HIGH PERVEANCE

The 6JB5 is a compactron beam pentode designed for use as the vertical-deflection amplifier in color television receivers.

Features of the 6JB5 include high perveance, high plate dissipation, a high voltage screen grid, and the utilization of a T-12 bulb to improve life and reliability by lowering operating temperature.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Compactron Beam Triode

6JD5

- COLOR TV TYPE
- 35 WATTS PLATE DISSIPATION
- DIFFUSION BONDED CATHODE
- TRANSCONDUCTANCE = 55000 MICROMHOS
- 300 MILLIAMPERES PEAK PLATE CURRENT

The 6JD5 is a compactron beam triode suited for use as a pulse-type high-voltage regulator in high-voltage power supply of color television receivers.

Features of the 6JD5 include a diffusion bonded cathode coating which provides a positive bond between the cathode coating and base material, thereby practically eliminating grid-to-cathode shorts caused by cathode flaking. By operating at a relatively low potential (3500 volts), this pulse-type regulator provides much less stress on internal components than shunt regulators operating in the 25000-volt range.

NOTES

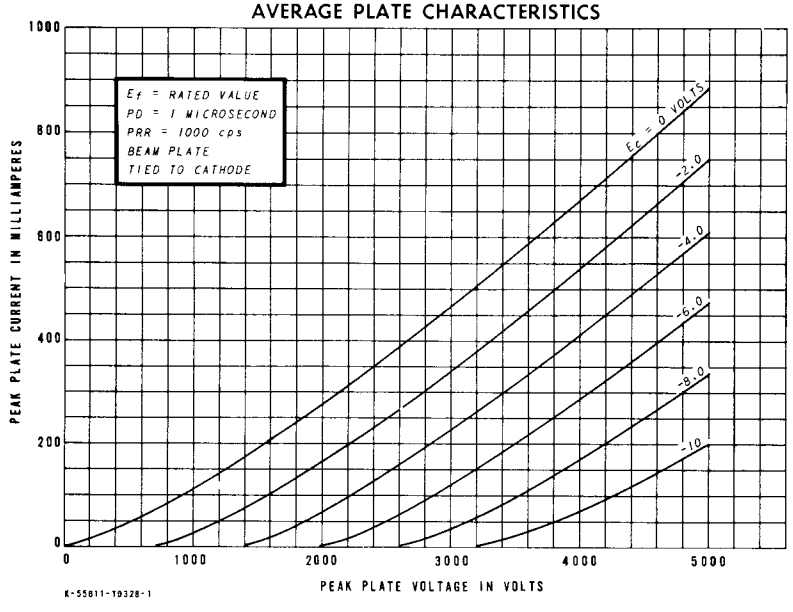
★ The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

● Heater current of a bogey tube at Ef = 6.3 volts.

♦ Without external shield.

§ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations", Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

⊕ Sufficient impedance (220 ohms by-passed with a 0.01 microfarad capacitor is suggested) should be in series with the cathode to limit the cathode current under prolonged heater-cathode short-circuit conditions. This protective impedance will minimize the danger of heater burnout in case of a momentary heater-cathode arc within the tube.



▲ Larger values of grid-circuit resistance may be used if provisions are made to protect the tube.

□ Duty cycle of the pulse must be less than 2.5 percent.

† Measured with an infrared themometer, Ircon Model 700 BC or equivalent, at an ambient temperature of 40° C.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

Beam Pentode

6JE6-C

FOR TV HORIZONTAL-DEFLECTION AMPLIFIER APPLICATIONS

COLOR TV TYPE | NOVAR CONSTRUCTION | T–12 ENVELOPE | WING FIN CONSTRUCTION

The 6JE6C is a beam pentode featuring Novar construction with a special plate fin. The fin provides improved heat distribution and a greater plate dissipation capability. This in turn increases reliability under rated conditions. It is designed for use as horizontal deflection amplifiers in color television receivers.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

6JH8
SHEET-BEAM TUBE

DESCRIPTION AND RATING

The 6JH8 is a miniature double-plate sheet-beam tube which incorporates a pair of balanced deflectors to direct the electron beam to either of the two plates and a control grid to vary the intensity of the beam. The resulting unique characteristics of this tube make it especially suited for service as a synchronous detector in color television receivers. In this application, relatively large, balanced output signals of both positive and negative polarities are developed which eliminate the need for phase-inversion functions in the matrix circuits. Other features of the 6JH8 synchronous detector circuit include low oscillator injection power requirements, freedom from the space-charge coupling effects which are present in dual-control pentodes and heptodes, linear output voltages, insensitiveness to variations in oscillator amplitude over a wide range, and a high ratio of plate to accelerator current. The 6JH8 is also suitable for service in the burst gate circuit of color TV receivers and a variety of other switching and gating applications.

Quadruple Diode

6JU8-A

The 6JU8-A is a general-purpose quadruple diode of the 9-pin miniature type designed for use in phase-detector and noise-immune color-killer circuits of color television receivers and in FM stereo multiplex equipment.

The 6JU8-A is electrically identical to the 6JU8, but is approximately 7/16" shorter for compact equipment designs.

NOTES

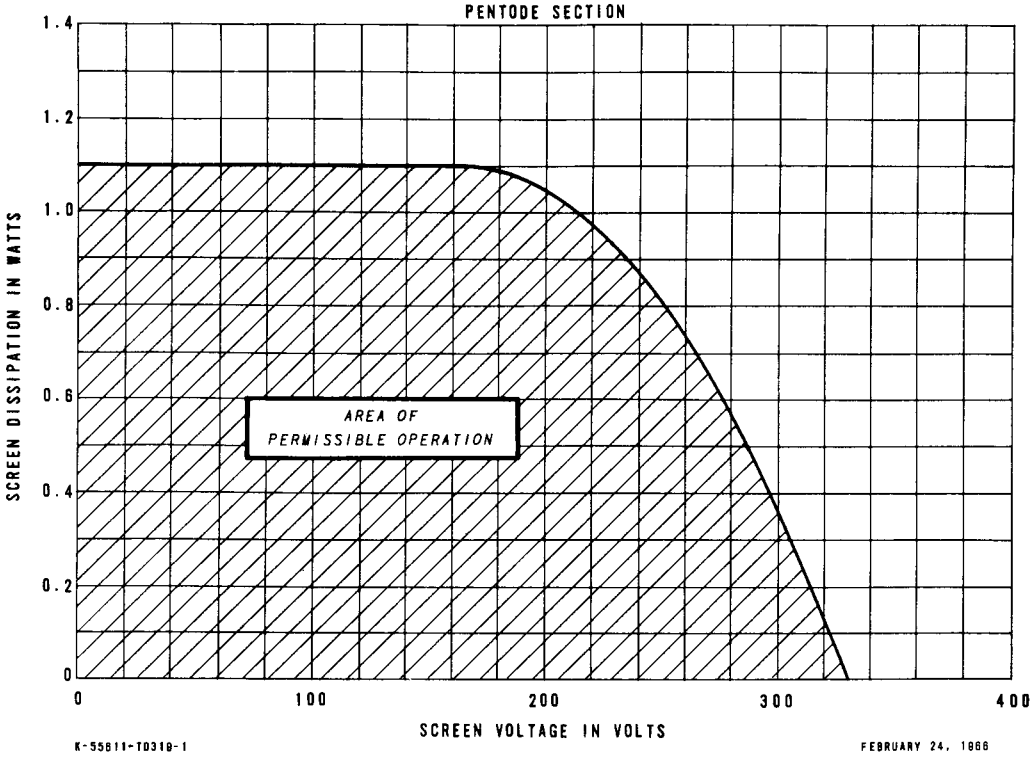
* Operated with the heater in series with the heaters of other tubes having the same bogey heater current.

‡ Operated with the heater in parallel with the heaters of other tubes having the same bogey heater voltage.

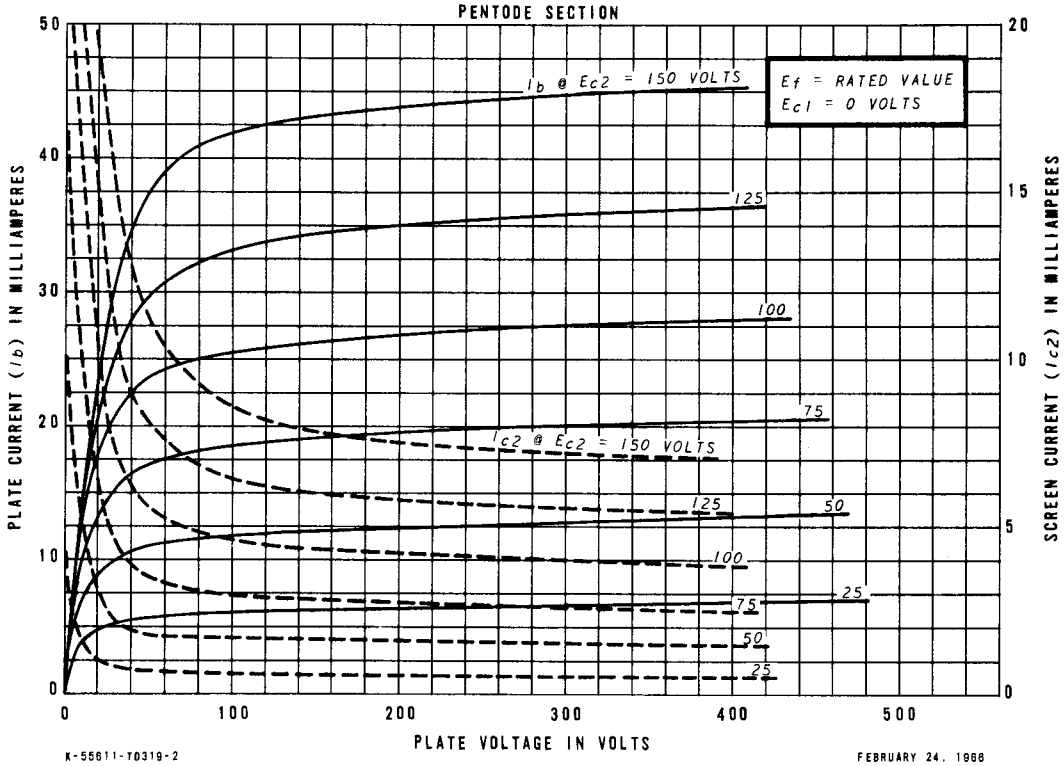
§ For parallel heater operation, the equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance; for series heater operation, the equipment designer should design the equipment so that heater current is centered at the specified bogey value, with heater supply variations restricted to maintain heater current within the specified tolerance.



¶ Heater current of a bogey tube at Ef = 6.3 volts.

\# The time required for the voltage across the heater to reach 80 percent of the bogey value after applying 4 times the bogey heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the bogey heater voltage divided by the bogey heater current.

Δ Without external shield.



** This value can be measured by a method involving a recurrent waveform such that the plate and screen dissipation will be kept within ratings in order to prevent damage to the tube.

MAXIMUM RATINGS (Cont'd)

Design-Center ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under normal conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube in average applications, making allowance for normal changes in operating conditions due to rated supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially no design-center value for the intended service is exceeded with a bogey tube under normal operating conditions at the stated normal supply voltage.

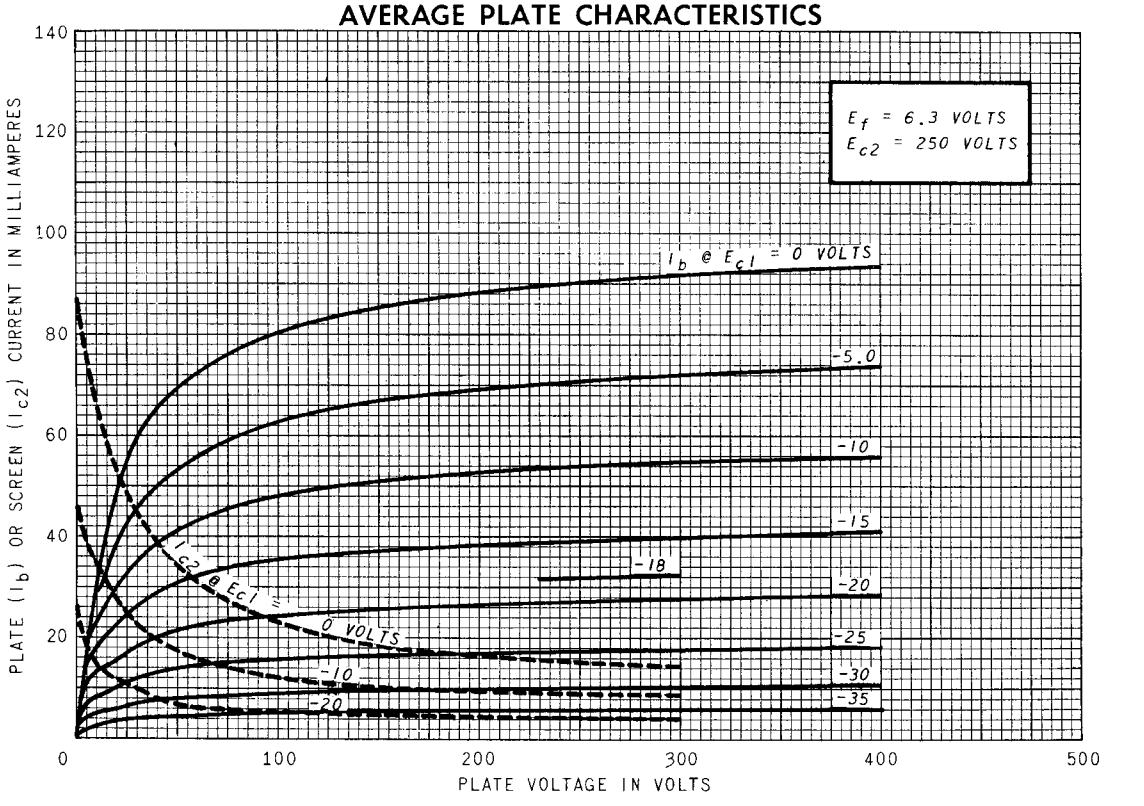
† *For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice for Television Stations; Federal Communications Commission". The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.*

▽ *Value given is to be considered as an Absolute Maximum Rating. In this case, the combined effect of supply voltage variation, manufacturing variation including components in the equipment, and adjustment of equipment controls should not cause the rated value to be exceeded.*



In stages operating with grid-leak bias, an adequate cathode-bias resistor or other suitable means is required to protect the tube in the absence of excitation.

§ *With screen tied to plate.*

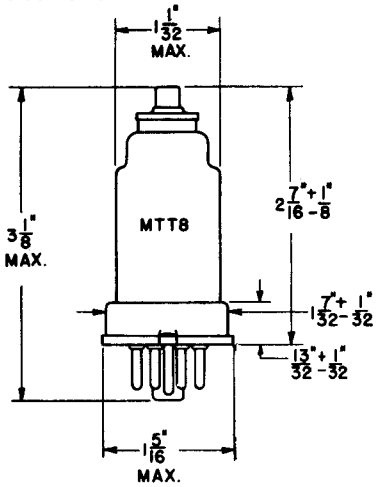
Description and Rating

RADIO-FREQUENCY-AMPLIFIER PENTODE



GENERAL DESCRIPTION

Principal Application: The 6K7 is a heater-cathode type pentode amplifier tube with remote cut-off characteristics and is designed for use as a radio-frequency or intermediate-frequency amplifier in a-c or storage battery operated equipment. Except for capacitances the electrical ratings and characteristics of the 6K7 are identical with those of types 78, 6K7-G, and 6K7-GT.

Cathode:	Coated Unipotential
Heater Voltage (A-C or D-C)	6.3 Volts
Heater Current	0.3 Ampere
Envelope:	MTT8 Metal Shell
Base:	B7-22 Small Wafer Octal 7-Pin Phenolic
Top Cap:	C1-4 Skirted Miniature

Mounting Position:	Any	
Direct Interelectrode Capacitances: *		
Grid Number 1 to Plate (Max)	0.005	μμf
Input	7	μμf
Output	12	μμf

Compactron Beam Pentode

6KD6

FOR TV HORIZONTAL-DEFLECTION AMPLIFIER APPLICATIONS

- COLOR TV TYPE
- 33 WATTS PLATE DISSIPATION
- 280 VOLTS B+
- 400 MILLIAMPERES DC CATHODE CURRENT
- OVER 1 AMPERE PEAK CURRENT

The 6KD6 is a compactron beam-power pentode primarily designed for use as the horizontal-deflection amplifier in color television receivers. It is characterized by having a very low knee with a very high peak current of over an ampere. This results in a basic capability to scan 90-degree large screen color picture tubes at 25 KV from 280-volt power supplies. Its low knee minimizes "snivets" without the necessity of supplying special voltages to the beam plates.

MAXIMUM RATINGS

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Electronic TUBES

6L6-GC

BEAM PENTODE

FOR AF POWER AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 6L6-GC is a beam-power pentode primarily designed for use in audio-frequency power amplifier applications. Features of the tube include high power output capabilities, high plate and screen dissipation ratings, high efficiency, high power sensitivity, and low distortion. The tube has the same characteristics as the 6L6-GB and may be used in any application for which the 6L6-GB is suitable. The higher ratings of the 6L6-GC, however, are advantageous where greater power-handling capability is required than is available with the GB version.

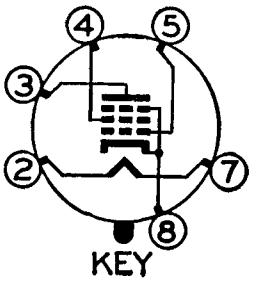
Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey tube of a specified type as defined by its published data, and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, taking responsibility for the effects of changes in operating conditions due to variations in tube characteristics.



The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, and environmental conditions.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

—PRODUCT INFORMATION—

Twin Pentode

6LE8

FOR COLOR DEMODULATOR APPLICATIONS

● COLOR TV TYPE ● HIGH LEVEL OUTPUT ● INTERNAL MATRIXING ● 11000 MICROMHOS

The 6LE8 is a miniature twin pentode having separate plates and number-3 grids for the two sections with a common screen, number-1 grid, and cathode. It is primarily designed for use as a color demodulator in color television receivers.

The high current of the 6LE8 provides enough voltage output to drive the grids of color picture tubes without further amplification. The common screen grid provides internal matrixing of the red and blue information to provide sufficient drive to the green gun.

The characteristics of the 6LE8 are such that it may be used in either of two modes; (1) chroma information to grid number 1 and two phases of reference signal to the two number-3 grids, or (2) reference signal to grid number 1 and two different phases of chroma information to the two number-3 grids.

Beam Triode

6LJ6-A

FOR HV SHUNT REGULATOR APPLICATIONS

■ COLOR TV TYPE ■ 27000 VOLTS DC ■ 40 WATTS PLATE DISSIPATION ■ X-RADIATION RATING

The 6LJ6-A is a low-current, high-voltage, beam triode intended for use as a shunt regulator in the high-voltage power supply of color television receivers.

The 6LJ6-A has a maximum d-c plate-voltage rating of 27,000 volts, a maximum d-c plate current rating of 1.5 milliamperes, and a maximum plate-dissipation rating of 40 watts.

Features of the 6LJ6-A include built-in X-radiation shielding and additional design and specification controls for the reduction of X-radiation output. The 6LJ6-A also features the utilization of a high voltage shield to minimize the effects of a momentary arc within the tube.

GENERAL ELECTRIC

MAXIMUM RATINGS (Cont'd)

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

CHARACTERISTICS AND TYPICAL OPERATION

AVERAGE CHARACTERISTICS

Unregulated DC Supply Voltage	36000	Volts
Equivalent Resistance of Unregulated Supply	11	Megohms
DC Reference Voltage	200	Volts
Equivalent Resistance of Reference Supply	1000	Ohms
Effective Grid-Plate Transconductance	200	Micromhos
DC Plate Current for Zero Load Current	1000	Microamperes
DC Plate Current for Load Current of 1 Milliampere	45	Microamperes
Regulated DC Output Voltage at Zero Load Current	25000	Volts
Regulated DC Output Voltage at Load Current of 1 Milliampere	24500	Volts

X-RADIATION RATING

X-radiation, maximum	0.5	mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 0.5 mR/hr at any time throughout their useful life, when operated within the maximum ratings, including heater voltage, specified on this data sheet.

This X-radiation maximum rating is based on data obtained with the use of the Victoreen 440 RF survey meter with a 3 3/8 inch aperture. X-radiation is measured with the face of the meter at a distance of 4 3/4 inches from the external surface of the tube. This rating information is not necessarily applicable when a different radiation measuring instrument or aperture is used.

Operation of the 6LJ6-A outside of the Absolute-Maximum Ratings indicated may damage the tube and/or result in either temporary or permanent changes in the X-radiation characteristics of the tube. Equipment design must be such that these Absolute-Maximum Ratings are not exceeded.

The above X-radiation characteristics are measured in accordance with JEDEC Publication No. 67, "Recommended Practice for Measurement of X-Radiation from Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73, "Recommended Practice for Quality Control of X-Radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein.

WARNING

X-RADIATION

Operation of the 6LJ6-A outside of the Absolute-Maximum Ratings indicated may produce soft X-rays above 0.5 milliroentgens per hour which may constitute a health hazard on prolonged exposure at close range unless the tube is adequately shielded. Equipment design must provide required shielding.

Precautions must be exercised during the servicing of equipment employing the 6LJ6-A to assure that the high voltage is adjusted to the recommended value and that any shielding components are replaced to their intended positions before the equipment is operated.

SHOCK HAZARD

The high voltages at which the 6LJ6-A is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and for the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 6LJ6-A in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

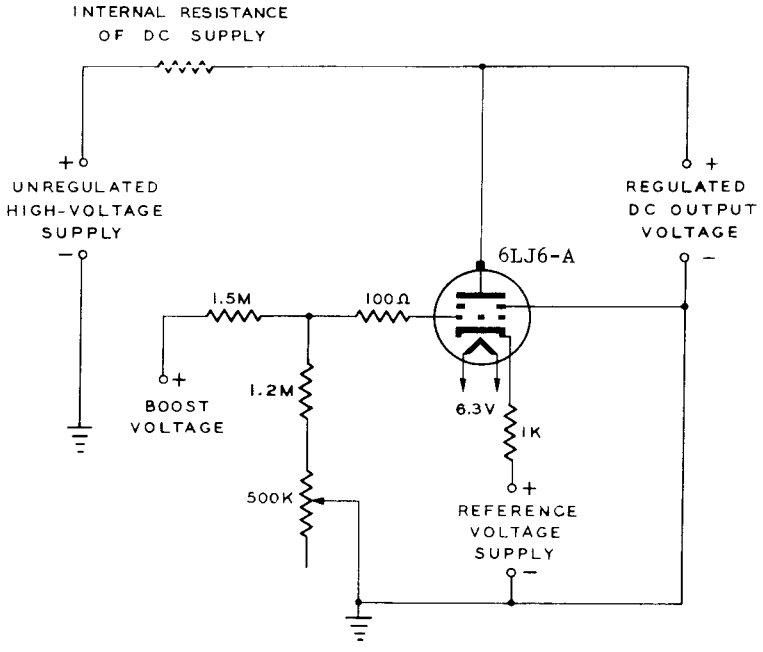
THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN

NOTES

* The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

‡ Heater current of a bogey tube at Ef = 6.3 volts.

§ Without external shield.



¶ Peak value for duration of 20 seconds maximum during equipment warmup.

\# Sufficient impedance (1000 ohms is recommended) should be in series with the cathode to limit the cathode current under prolonged heater-cathode short-circuit conditions to 450 ma. This protective impedance will minimize the danger of heater burnout in case of a momentary heater-cathode arc within the tube.

Δ With flyback transformer high-voltage supply.

¢ Shield connected directly to ground to minimize the effects of a momentary arc within the tube.

TYPICAL SHUNT REGULATOR CIRCUIT

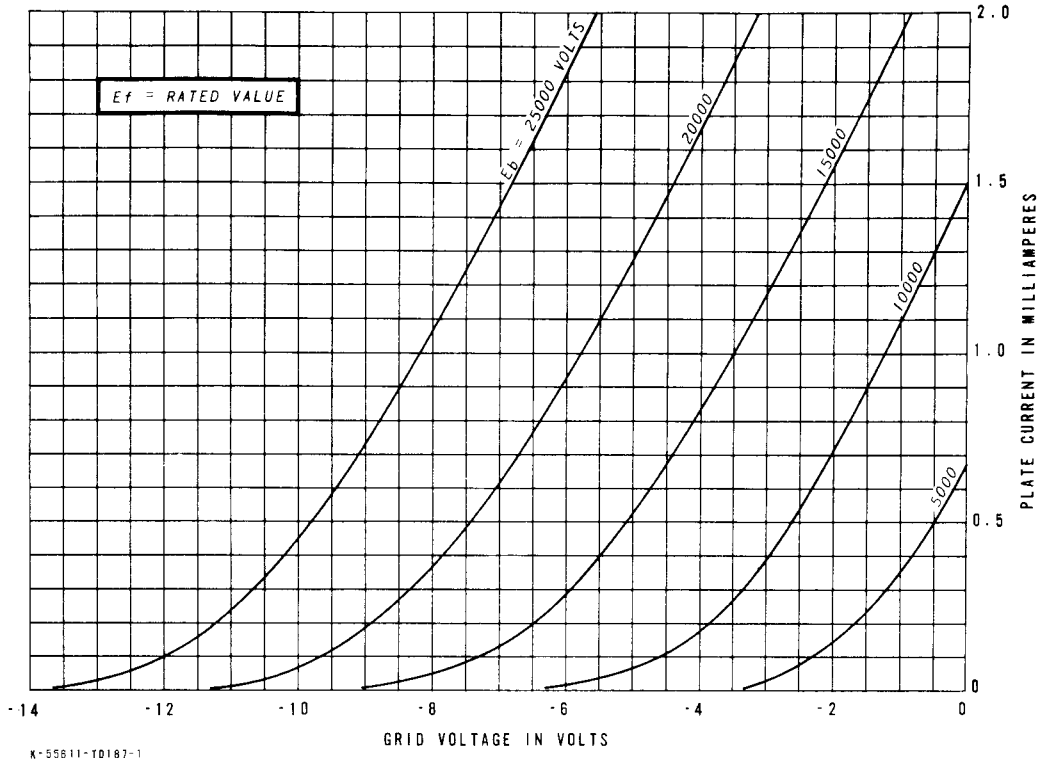
APPLICATION CONSIDERATIONS

The base pins of the 6LJ6-A fit the standard octal socket. Socket terminals for pins 1, 4, and 8 should not be used for tie points. Tube performance may be adversely affected should this precaution not be followed.

Sufficient impedance (1000 ohms is suggested) should be in series with the cathode to limit the cathode current under prolonged heater-cathode short circuit conditions to 450 ma. This protection impedance will minimize the danger of heater burnout in case of a momentary heater-cathode arc within the tube.

A unique design feature of the 6LJ6-A is the utilization of a high voltage shield to minimize the effects of a momentary arc within the tube. This shield is brought out to a separate pin so that it can be tied directly to ground, whereas it has been customary in the more conventional tubes of this type to tie the shield directly to the cathode. When the shield is tied to the cathode, any arcing can cause failure of the cathode resistor and/or breakdown of the heater cathode insulation, failures which the 6LJ6-A has been designed to prevent.

The high voltages at which the 6LJ6-A is operated may be very hazardous. Extreme caution should be used while making any circuit adjustments. The 6LJ6-A and all of its associated hardware should be housed in a protective enclosure. It is particularly important that all parts which may be at a high potential with respect to ground be housed in this protective enclosure. The protective enclosure should be constructed with a system of interlocks to prevent anyone from coming in contact with any high potential point in the electrical system. The interlocks should break the primary circuit of the high-voltage supply when any part of the protective enclosure is open, and should prevent the closing of the primary circuit until the protective enclosure is closed and locked.



High voltages may appear at points in the circuit which are normally at low potentials as a result of improper circuit connection or of capacitor breakdown. Therefore, before touching any part of the circuit, the power supply switch should be turned off and both terminals of any capacitor should be grounded.

The bulb of the 6LJ6-A becomes hot during operation. Therefore, it is essential that provision be made for free circulation of air around the tube in order to insure sufficient cooling.

The plate of the 6LJ6-A exhibits a dull red color when the tube is operated at maximum plate dissipation. In addition, it may exhibit a bluish glow on the upper half of the bulb inner wall surface during normal operation. This bluish glow is a result of fluorescence and it should not be mistaken for gas.

To prevent any strain from being exerted on the seal of the plate cap, it is important that connection to the plate cap be made by an appropriate connector which has a flexible lead.

AVERAGE TRANSFER CHARACTERISTICS

6LQ6

FOR TV HORIZONTAL-DEFLECTION AMPLIFIER APPLICATIONS

DARK HEATER | PLATE CURRENT 30 WATTS | NOVAR TYPE | OVERLOAD Pb 200 WATTS

The 6LQ6 is a double–ended high perveance beam power pentode. This tube is especially useful as a horizontal–deflection amplifier tube in color–TV receivers.

Features of the 6LQ6 are, the endurance of excessive plate dissipation, the withstanding of a 200 watt plate dissipation for a period of time sufficient enough to permit conventional receiver protection devices to function and the capability to meet the stringent requirements of color–television deflection circuits.

NOTES

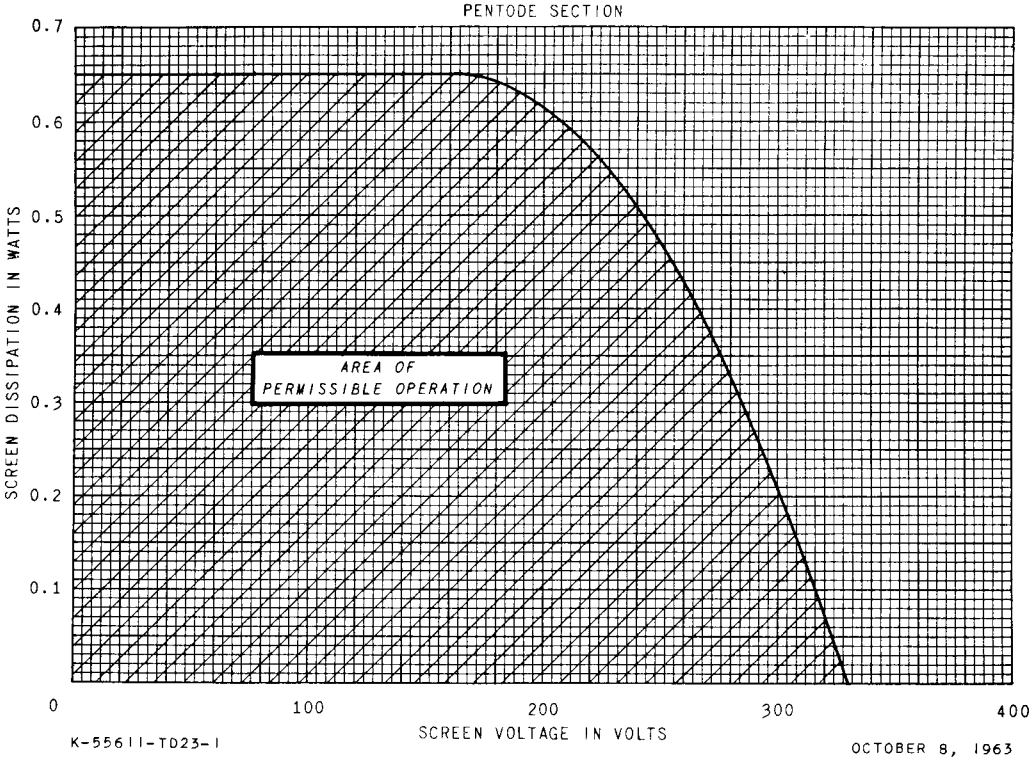
* Operated with the heater in series with the heaters of other tubes having the same bogey heater current.

‡ Operated with the heater in parallel with the heaters of other tubes having the same bogey heater voltage.

§ For parallel heater operation, the equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

¶ For series heater operation, the equipment designer should design the equipment so that heater current is centered at the specified bogey value, with heater supply variations restricted to maintain heater current within the specified tolerance.

Heater current of a bogey tube at Ef = 6.3 volts.



Δ The time required for the voltage across the heater to reach 80 percent of the bogey value after applying 4 times the bogey heater voltage to a circuit consisting of the tube heater in series with a resistance equal to 3 times the bogey heater voltage divided by the bogey heater current.

** Without external shield.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

MAXIMUM RATINGS (Cont'd)

Design-Center ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under normal conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube in average applications, making allowance for normal changes in operating conditions due to rated supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially no design-center value for the intended service is exceeded with a bogey tube under normal operating conditions at the stated normal supply voltage.

—PRODUCT INFORMATION—

Beam Triode

6MA6

FOR HV SHUNT REGULATOR APPLICATIONS

■ COLOR TV TYPE ■ 30000 VOLTS DC ■ 40 WATTS PLATE DISSIPATION ■ X-RADIATION RATING

The 6MA6 is a low current, high-voltage, beam triode intended for use as a shunt regulator in the high-voltage power supply of color television receivers.

The 6MA6 has a maximum d-c plate-voltage rating of 30,000 volts, a maximum d-c plate current rating of 1.5 milliamperes, and a maximum plate-dissipation rating of 40 watts.

Features of the 6MA6 include built-in X-radiation shielding and additional design and specification controls for the reduction of X-radiation output to low levels even under conditions of equipment misadjustment and/or circuit failure mode operation.

MAXIMUM RATINGS (Cont'd)

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

CHARACTERISTICS AND TYPICAL OPERATION

AVERAGE CHARACTERISTICS

Unregulated DC Supply Voltage	36000	Volts
Equivalent Resistance of Unregulated Supply	11	Megohms
DC Reference Voltage	200	Volts
Equivalent Resistance of Reference Supply	1000	Ohms
Effective Grid-Plate Transconductance	200	Micromhos
DC Plate Current for Zero Load Current	1000	Microamperes
DC Plate Current for Load Current of 1 Milliampere	45	Microamperes
Regulated DC Output Voltage at Zero Load Current	25000	Volts
Regulated DC Output Voltage at Load Current of 1 Milliampere	24500	Volts

X-RADIATION RATING

	Maximum Plate Voltage	Maximum DC Plate Current	Maximum X-Radiation Output
X-radiation, maximum	27 KV	1.5 mA	0.5 mR/hr
	30 KV	1.3 mA	0.5 mR/hr

Based on accumulated sample test data taken initially and during life test, tubes do not exceed the maximum rating limit of 0.5 mR/hr at any time throughout their useful life when operated within the maximum ratings, including heater voltage, specified on this data sheet.

This X-radiation maximum rating is based on the use of the Victoreen 440 RF/C survey meter as the standard instrument for X-radiation measurement. X-radiation is measured with the plastic spacer of the 440 RF/C survey meter at a distance of four (4) inches from the external surface of the tube under test. This rating information is not necessarily applicable when a different radiation measuring instrument is used.

Sustained operation of the 6MA6 outside of the Absolute-Maximum Values indicated may damage the tube and/or result in either temporary or permanent changes in the X-radiation characteristics of the tube. Equipment design must be such that these Absolute Maximum Ratings are not exceeded over the worst probable range of adjustments and operating conditions for the set.

The X-radiation characteristics are measured in accordance with JEDEC Publication No. 67A, "Recommended Practice for Measurement of X-Radiation from Receiving Tubes," and controlled in accordance with JEDEC Publication No. 73A, "Recommended Practice for Quality Control of X-Radiation from High Voltage Rectifier and Shunt Regulator Receiving Tubes."

The General Electric Company makes no representation concerning the X-radiation output from these tubes when operated beyond the maximum ratings set forth herein, except as noted under "X-Radiation Characteristics."

X-RADIATION CHARACTERISTICS

EQUIPMENT MISADJUSTMENT AND/OR CIRCUIT FAILURE MODE OPERATION

The 6MA6 will produce varying levels of X-radiation depending upon operating conditions. Based on known attenuation factors of the tube construction materials and accumulated sample test data taken initially and during life test, X-radiation is not expected to exceed 0.5 mR/hr under equipment misadjustment and/or circuit failure mode operation of plate voltage and current listed below.

Maximum Plate Voltage	Maximum DC Plate Current	Maximum Expected X-Radiation Output
35 KV	0.1 mA	0.5 mR/hr
34 KV	0.3 mA	0.5 mR/hr
29 KV	1.5 mA	0.5 mR/hr

WARNING

X-RADIATION

Operation of the 6MA6 above the Maximum conditions shown for equipment misadjustment and/or circuit failure mode operation conditions may produce soft X-rays above 0.5 milliroentgens per hour which may constitute a health hazard on prolonged exposure at close range unless the tube is adequately shielded. Equipment design must provide required shielding.

Precautions must be exercised during the servicing of equipment employing the 6MA6 to assure that the high voltage is adjusted to the recommended value and that any shielding components are replaced to their intended positions before the equipment is operated.

SHOCK HAZARD

The high voltages at which the 6MA6 is operated can be extremely dangerous to the user or serviceman. Extreme care should be taken in the use of and in the servicing and adjustment of any high voltage circuit.

Precautions must be exercised during the replacement or servicing of the 6MA6 in equipment to assure that the high voltage output terminal is properly grounded while inserting or removing the tube from its socket or while connecting or disconnecting the top cap connector.

THE EQUIPMENT MANUFACTURER SHOULD PROVIDE A WARNING LABEL IN AN APPROPRIATE POSITION ON THE EQUIPMENT TO ADVISE THE SERVICEMAN OF ALL PRECAUTIONS HEREIN.

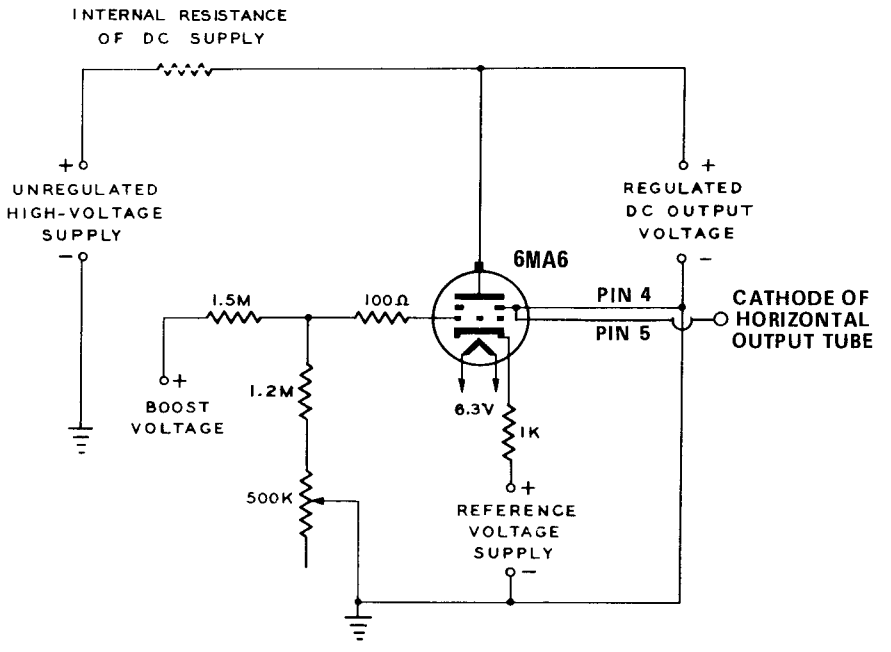
NOTES

★ The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

● Heater current of a bogey tube at Ef = 6.3 volts.

▲ Without external shield.

♦ Shield should be connected directly to ground to minimize the effects of a momentary arc within the tube.



§ Peak value for duration of 20 seconds maximum during equipment warmup.

⊕ Sufficient impedance (1000 ohms is suggested) should be in series with the cathode to limit the cathode current under prolonged heater-cathode short-circuit conditions to 450 ma. This protective impedance will minimize the danger of heater burnout in case of a momentary heater-cathode arc within the tube.

□ With flyback transformer high voltage supply.

† Measured with an infrared thermometer, Ircon Model 700 BC or equivalent, at an ambient temperature of 40° C.

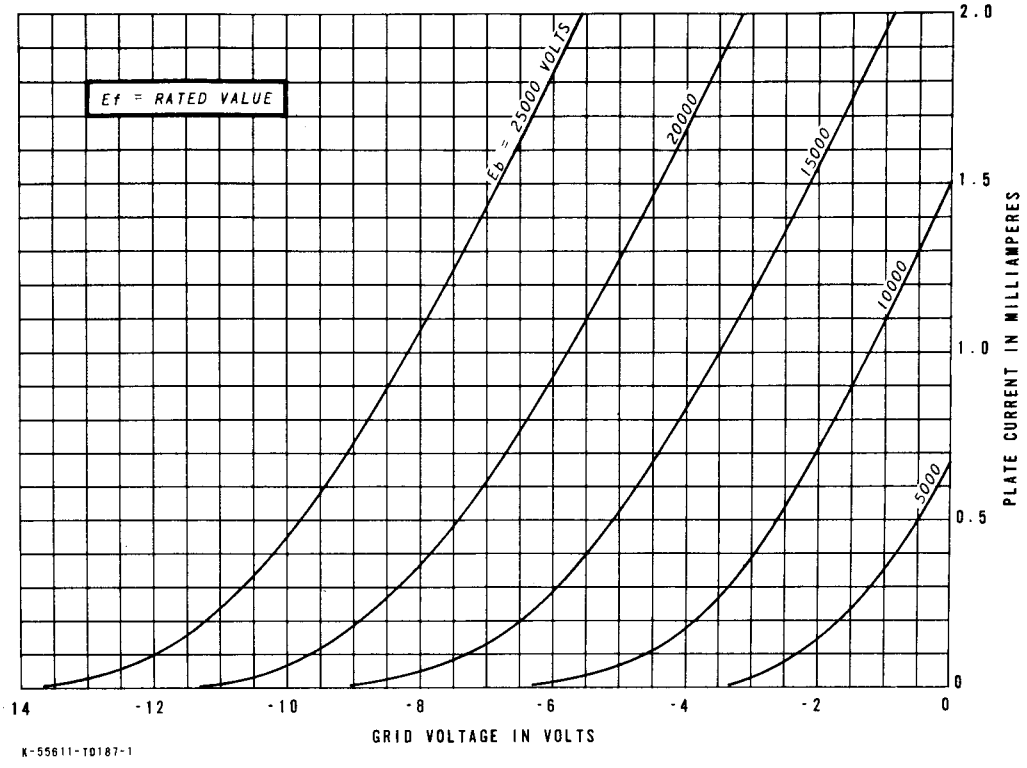
TYPICAL SHUNT REGULATOR CIRCUIT

APPLICATION CONSIDERATIONS

The base pins of the 6MA6 fit the standard octal socket. Socket terminals for pins 1 and 2 should not be used for tie points. Tube performance may be adversely affected should this precaution not be followed. It is permissible to tie the cathode of the horizontal output tube to pin 5 of the 6MA6 for circuit connection to ground.

Sufficient impedance (1000 ohms is suggested) should be in series with the cathode to limit the cathode current under prolonged heater-cathode short-circuit conditions to 450 ma. This protective impedance will minimize the danger of heater burnout in case of a momentary heater-cathode arc within the tube.

The high voltages at which the 6MA6 is operated may be very hazardous. Extreme caution should be used while making any circuit adjustments. The 6MA6 and all of its associated hardware should be housed in a protective enclosure. It is particularly important that all parts which may be at a high potential with respect to ground be housed in this protective enclosure. The protective enclosure should be constructed with a system of interlocks to prevent anyone from coming in contact with any high potential point in the electrical system. The interlocks should break the primary circuit of the high-voltage supply when any part of the protective enclosure is open, and should prevent the closing of the primary circuit until the protective enclosure is closed and locked.



High voltages may appear at points in the circuit which are normally at low potentials as a result of improper circuit connection or of capacitor breakdown. Therefore, before touching any part of the circuit, the power supply switch should be turned off and both terminals of any capacitor be grounded.

The bulb of the 6MA6 becomes hot during operation. Therefore, it is essential that provision be made for free circulation of air around the tube in order to insure sufficient cooling.

The plate of the 6MA6 exhibits a dull red color when the tube is operated at maximum plate dissipation. In addition, it may exhibit a bluish glow on the upper half of the bulb inner wall surface during normal operation. This bluish glow is a result of fluorescence and it should not be mistaken for gas.

To prevent any strain from being exerted on the seal of the plate cap, it is important that connection to the plate cap be made by an appropriate connector which has a flexible lead.

Compactron Beam Pentode

6MH6

FOR TV HORIZONTAL-DEFLECTION AMPLIFIER APPLICATIONS

- COLOR TV TYPE
- 38.5 WATTS PLATE DISSIPATION
- 280 VOLTS B+
- 500 MILLIAMPERES DC CATHODE CURRENT
- OVER 1 AMPERE PEAK CURRENT

The 6MH6 is a compactron beam–power pentode primarily designed for use as the horizontal–deflection amplifier in color television receivers. It is characterized by having a very low knee with a very high peak current of over an ampere. This results in a basic capability to scan 90–degree large screen color picture tubes at 26 KV from 280–volt power supplies. Its low knee minimizes "snivets" without the necessity of supplying special voltages to the beam plates.

NOTES

♦ Publication of these data does not obligate the General Electric Company to manufacture a tube with these characteristics.

* The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

● Heater current of a bogey tube at Ef=6.3 volts.

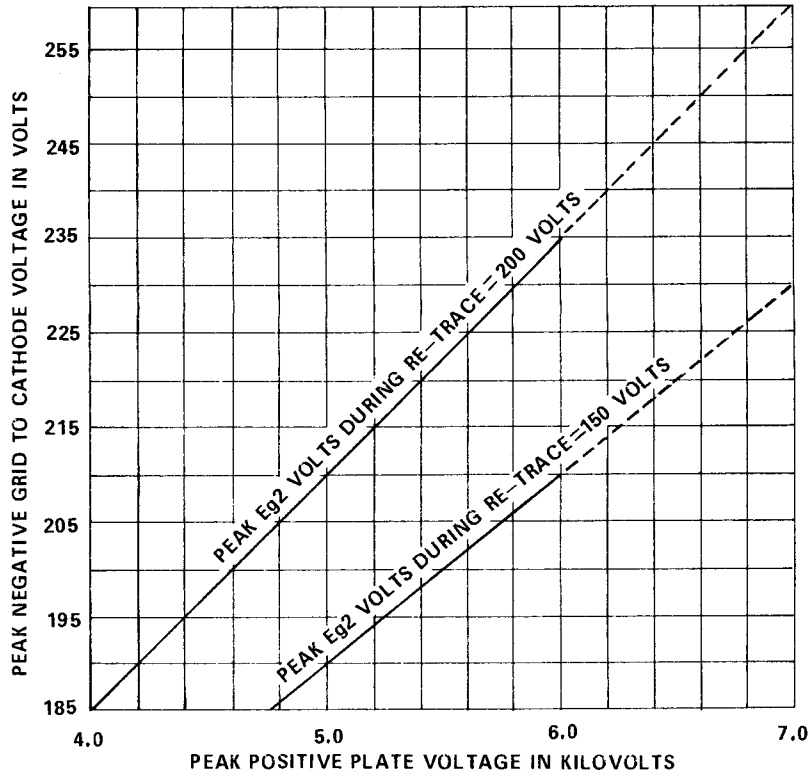
♦ Without external shield.

▲ For operation in a 525–line, 30–frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations", Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

□ In stages operating with grid–leak bias, an adequate cathode–bias resistor or other suitable means is required to protect the tube in the absence of excitation.

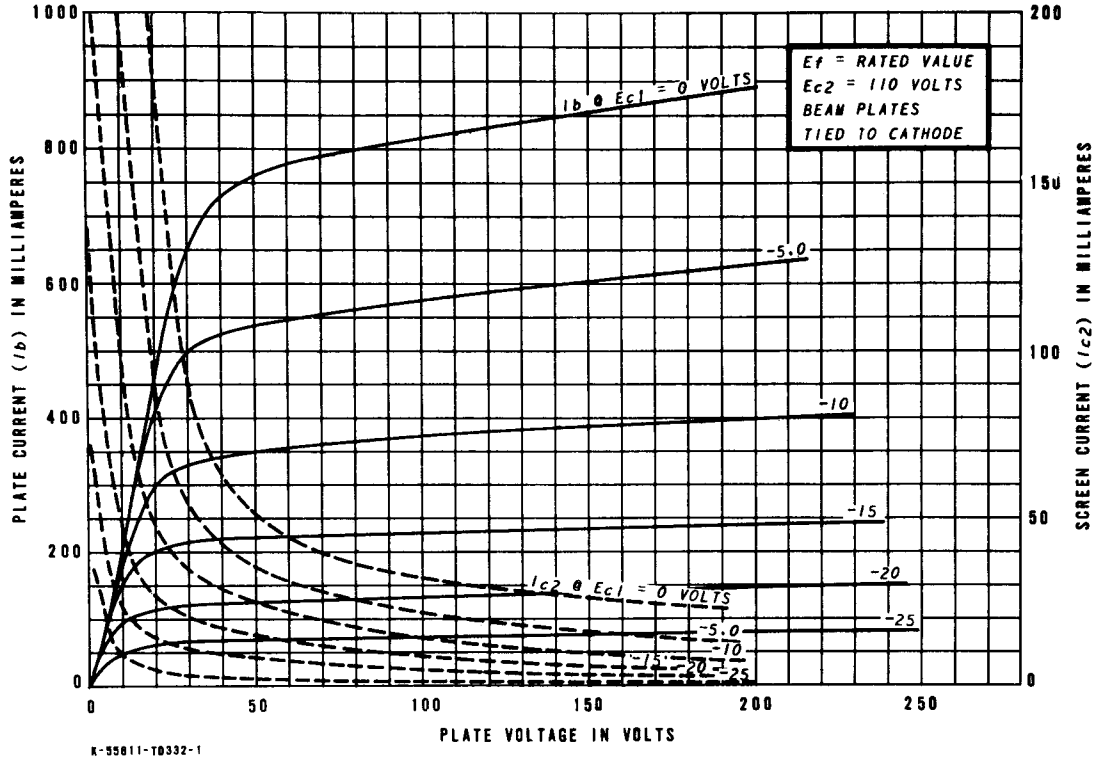
¶ Resistance up to 10,000 ohms is permitted providing the positive beam plate voltage does not ecceed the rated value. Bypassing the resistor in the beam plate circuit is not recommended,

§ The circuit design has to be such that negative control grid currents up to 5 microamperes do not have any detrimental effect upon tube adjustment or circuit performance. Care should be taken so that the limiting values for plate dissipation, screen dissipation, and cathode current are not exceeded with 5 microamperes grid current.



⊕ Measured with an infrared themometer, Ircon Model 700 BC or equivalent.

† Values measured by a method involving a recurrent waveform such that the plate and screen dissipation will be kept within rating in order to prevent damage to the tube.



‡ Triode connection (screen tied to plate) with Eb=Ec2=175 volts, and Ec1= –21 volts.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

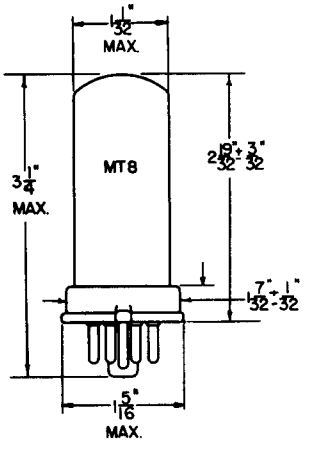
Description and Rating



POWER-AMPLIFIER TWIN TRIODE

GENERAL DESCRIPTION

Principal Application: The 6N7 is a heater-cathode type twin triode designed for use as a class B power amplifier in the output stage of a-c or battery operated equipment. It may also be used in other applications such as a biased detector, oscillator phase inverter or class A amplifier. The 6N7 electrical ratings and characteristics are identical with those of the 6A6 and 6N7-G.

Cathode:	Coated Unipotential
Heater Voltage (A-C or D-C)	6.3 Volts
Heater Current	0.8 Ampere

Amplification Factor	35	35	
Plate Resistance	11300	11000	Ohms
Transconductance	3100	3200	Micromhos
Plate Current	6	7	Milliamperes

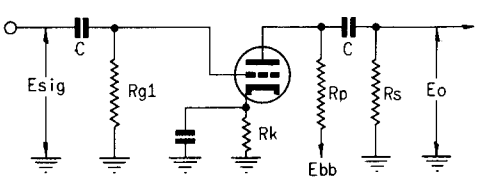
Note:

Approximately 20 watts power output may be obtained in a class B output stage by using two 6N7 tubes with the units of each tube connected in parallel and operated with 300 volts on each plate and with a 5000-ohm plate-to-plate load.

** *Unless otherwise specified the values shown are for the two units.*

* *Includes peak voltage drop through the grid circuit impedance.*

° *For values of power output shown.*



§ *At 400 cycles for class B stage in which the effective resistance per grid circuit is 500 ohms, and the leakage reactance of the coupling transformer is 50 millihenrys.*

Δ *Triode units connected in parallel.*

φ *The d-c resistance in the grid circuit of the 6N7 as a class A amplifier should not exceed 0.5 megohm for self-bias operation and 0.1 megohm for fixed bias operation.*

Electronic TUBES

6S4-A

TRIODE

FOR TV VERTICAL-DEFLECTION AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 6S4-A is a miniature medium-mu triode for use as the vertical-deflection amplifier in television receivers. The tube features relatively high plate current at low plate voltages and is capable of withstanding the high pulse voltages normally encountered in this application.

The 6S4-A also exhibits a controlled heater warm-up characteristic which makes it especially suited for use in television receivers which employ series-connected heaters. When the 6S4-A is used in conjunction with other 600-milliampere types which exhibit essentially the same heater warm-up characteristic, heater voltage surges across the individual tubes are minimized during the warm-up period.

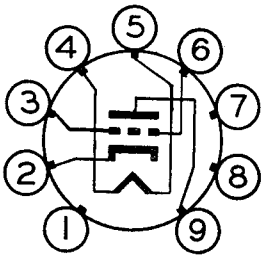
Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey tube of a specified type as defined by its published data, and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, taking responsibility for the effects of changes in operating conditions due to variations in tube characteristics.



The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, and environmental conditions.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

Electronic TUBES

6SN7-GTB—6SN7-GTA—12SN7-GTA

TWIN TRIODE

DESCRIPTION AND RATING

The 6SN7-GTB is a medium-mu twin triode suitable for use in a wide variety of general-purpose amplifier and phase-inverter applications. It is also especially useful as a blocking oscillator, multivibrator, or vertical-deflection amplifier in television receivers.

Electrically and physically the 6SN7-GTB is a replacement for the 6SN7-GTA. In addition, however, the 6SN7-GTB exhibits a controlled heater warm-up characteristic which makes the tube especially suited for use in television receivers which employ series-connected heaters. When the 6SN7-GTB is used in conjunction with other 600-milliampere types which have essentially the same heater warm-up characteristic, heater voltage surges across the individual tubes are minimized during the warm-up.

Except for heater and heater warm-up time ratings, the 12SN7-GTA is identical to the 6SN7-GTB.

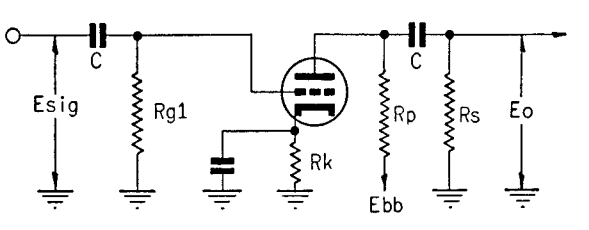
* Heater warm-up time is defined as the time required in the circuit shown at the right for the voltage across the heater terminals to increase from zero to the heater test voltage (V_1). For this type, E = 25 volts (RMS or DC), V_1 = 5.0 volts (RMS or DC), and R = 31.5 ohms.

† Without external shield.

‡ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.



§ Value given is to be considered as an Absolute Maximum Rating. In this case, the combined effect of supply voltage variation, manufacturing variation including components in the equipment, and adjustment of equipment controls should not cause the rated value to be exceeded.

π In stages operating with grid-leak bias, an adequate cathode-bias resistor or other suitable means is required to protect the tube in the absence of excitation.

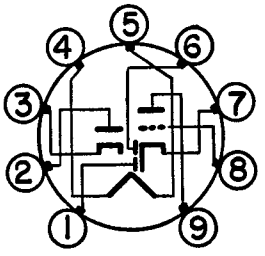
6T8—5T8—19T8



TRIPLE-DIODE TRIODE

DESCRIPTION AND RATING

The 6T8 is a miniature triple-diode, high-mu triode intended primarily for use as a combined AM detector, FM detector, and audio-frequency voltage amplifier in radio and television receivers. For flexibility in circuit design, one of the three high-perveance diodes is provided with a separate cathode connection.

The 5T8, 6T8, and 19T8 are alike except for heater ratings and heater-cathode voltage ratings. The 19T8 is particularly suited for use in a-c/d-c radio receivers; while the 5T8, as a result of its controlled heater warm-up characteristic, is especially well suited for use in television receivers which employ series-connected heaters. When the 5T8 is used in conjunction with other 600-milliampere types which exhibit essentially the same heater warm-up characteristic, heater voltage surges across the individual tubes are minimized during the warm-up period.

MAXIMUM RATINGS

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

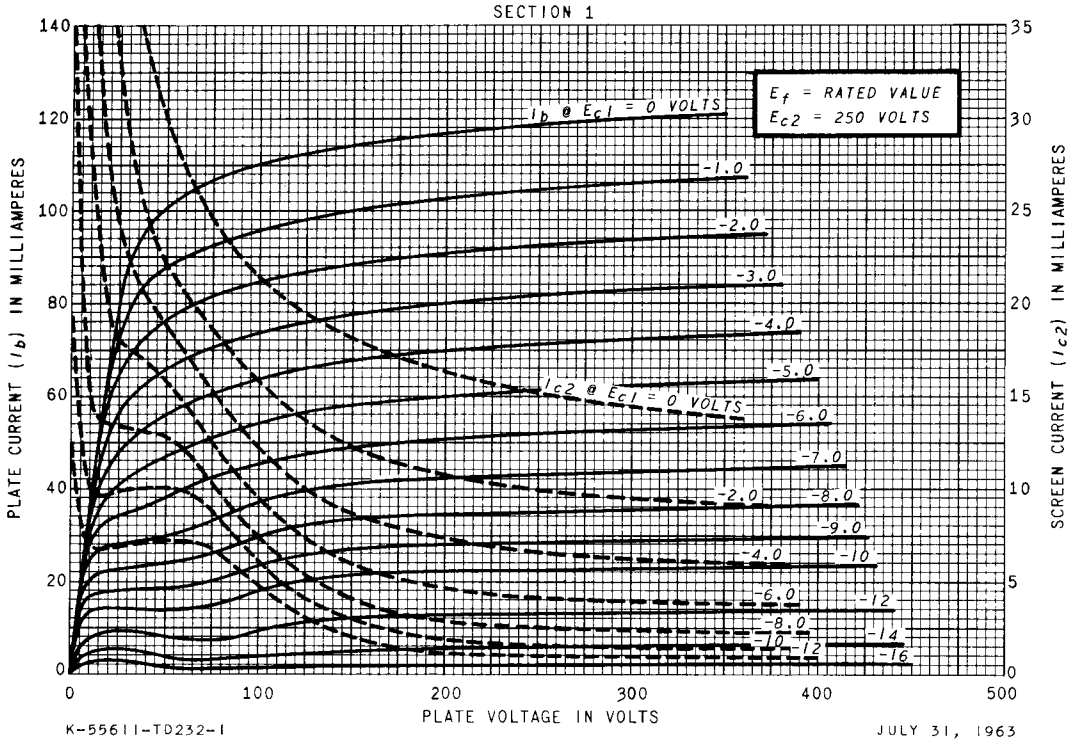
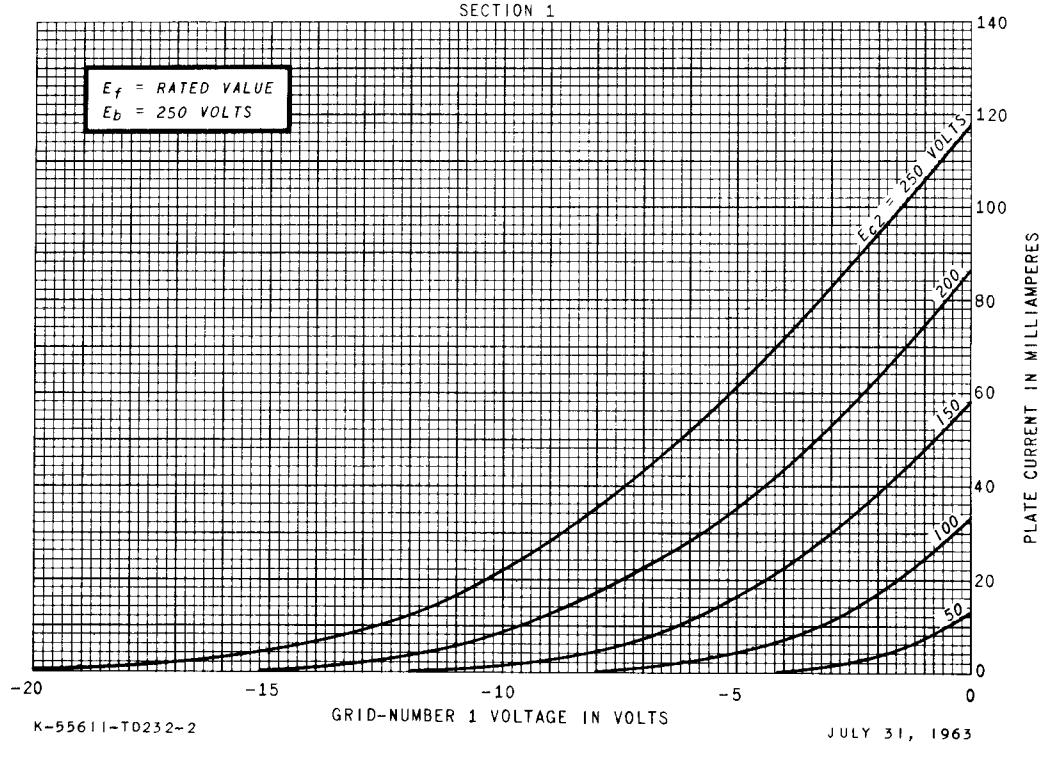
NOTES



* The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

† Heater current of a bogey tube at Ef = 6.3 volts.



‡ Without external shield.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

Electronic TUBES

6U8-A/5U8

TRIODE-PENTODE

DESCRIPTION AND RATING

The 6U8-A is a miniature tube which contains a sharp-cutoff pentode and a medium-mu triode in one envelope. Each section has a separate cathode and is electrically independent. The tube is primarily intended for service as a combined triode oscillator and pentode mixer in television and FM receivers, although it is also suitable for a wide variety of general-purpose applications.

Except for heater ratings, the 5U8 is identical to the 6U8-A.
