Grid Recovery

Change in Average Plate Current	0.6	Milliamperes
Peak Plate Current Backswing	1.0	Milliamperes

Tubes with poor grid recovery affect circuit operation, when the grid is driven positive by a pulse of signal or noise, somewhat as if a parallel RC circuit were in series with the grid. This effect may occur in tubes of any type, but is unimportant in many applications. In the majority of 7077 tubes the effect is negligible, but to eliminate the few in which it may be excessive, tubes are tested under the following conditions: Ef = 6.3 volts, Ebb = 250 volts, R_L = 0.01 meg. Ec is adjusted for Ib = 3.0 ma.

Upon application to the grid of a 5 volts positive pulse (prr = 60 pps, duty factor = 0.0012) the change in average plate current is noted, and the peak plate current backswing is measured. The following diagram shows qualitatively the plate current-time relationship for a tube (with poor grid recovery) subjected to this test.

PLATE CURRENT VS. TIME
—GRID RECOVERY TEST

	Min.	Bogey	Max.	
Low Frequency Vibrational Output			10	Millivolts RMS

Statistical sample is subjected to vibration in each of two planes at 40 cps, with peak acceleration 15G. Tube is operated with Ef = 6.3 volts, Ebb = 150 volts, Rk = 82 ohms (bypassed), R_L = 10000 ohms.

Variable Frequency Vibrational Output

The tube is designed to be free of vibrational outputs in excess of 15 mv RMS at any frequency within the range 100–2000 cps, when vibrated in either of two planes at 10G peak acceleration. Electrical conditions for this test are the same as for Low Frequency Vibrational Output.

Low Pressure Voltage Breakdown Test

Statistical sample tested for voltage breakdown at a pressure of 8mm Hg, to simulate an altitude of 100,000 feet. Tubes shall not give visual evidence of flashover or corona when 300 volts RMS, 60 cps, is applied between the plate and grid terminals.

DEGRADATION RATE TESTS

Fatigue

Statistical sample vibrated for a total of 96 hours, 48 hours in each of two planes, at a peak acceleration of 10G. Frequency is 60 cps. Tubes are operated during the test with Ef = 6.3 volts (no other voltages applied). Following the test, tubes are evaluated for low frequency vibrational output, heater-cathode leakage, heater current, noise figure, and gain.

Shock

Statistical sample subjected to 5 impact accelerations of approximately 450G in each of four positions. The accelerating forces are applied by the Navy-type, High Impact (flyweight) Shock Machine using a 30° hammer angle. Tubes are operated during the test with Ef = 6.3 volts, Eb = 150 volts, Ehk = +100 volts, and Rk = 82 ohms. Following the test, tubes are evaluated for low frequency

from JETEC release #2016, Dec. 16, 1957

GL-7085

TRIODE

The GL-7085 is a three-electrode tube designed for induction and dielectric heating as well as broadcast use. A thoriated-tungsten-filament version of the GL-880, the tube features a free-hung or self-supporting filament and a glass envelope incorporating rugged fernico-to-glass seals throughout. The anode is water cooled and is capable of dissipating 22.5 kilowatts with a water flow of approximately 12 gallons per minute. Maximum ratings of 12.5 kilovolts d-c plate voltage and 60 kilowatts plate input apply at frequencies up to 25 megacycles; operation at 50 megacycles is permissible with voltage and input reduced to three-quarters maximum ratings.

* This flow for jackets with spiral water deflector. Older straight-wall jackets will require 16.2 gallons per minute at 22.5 kilowatts.

/ At frequencies above 10 megacycles special attention should be given to adequate ventilation of the dish and seals to keep the temperature at the hottest point below 165 C. Heat-radiating connectors for grid and filament posts are recommended when tube operation is at frequencies greater than 10 megacycles.

‡ Averaged over any audio-frequency cycle of sine-wave form.

§ The driving stage should have good regulation and should be capable of supplying considerably more than the specified driving power.

ø Subject to wide variations depending on the impedance of the load circuit. High-impedance load circuits require more grid current and driving power to obtain the desired output. Low-impedance circuits require less grid current and driving power but sacrifice plate-circuit efficiency. The driving stage should have a tank circuit with good regulation and should be capable of supplying considerably more than the required driving power.

Δ At crest of audio-frequency cycle with modulation factor of 1.0.

** Obtained by grid resistor of 1075 ohms or by partial self-bias methods.

*** Modulation essentially negative may be used if the positive peak of the audio-frequency envelope does not exceed 115 percent of the carrier conditions.

MAXIMUM FREQUENCY VS RATINGS

The GL-7085 will operate at maximum ratings in all classes of service at frequencies as high as 25 megacycles. The tube will operate at higher frequencies provided the maximum values of plate voltage and plate input are reduced according to the tabulation below. In Class C Telegraphy service at frequencies below 2 megacycles, the plate voltage and input can be increased as indicated over the maximum values permissible at 25 megacycles.

Frequency Megacycles	Class of Service	Percentage of Maximum Rated Plate Voltage and Plate Input	
		Plate Voltage	Plate Current
25	B, C - Telephony, C - Telegraphy	100	100
50	B	80	94
	C - Telephony	75	75
	C - Telegraphy	75	75
2	C - Telegraphy	120	112.5

GL-7151

IGNITRON

DESCRIPTION AND RATING

The GL-7151 is a sealed water-cooled ignitron with a stainless-steel jacket for a-c control service. In such application two tubes in an inverse-parallel connection will control 4800 kilovolt-amperes at voltages of 250 to 500 volts over a frequency range of 25 to 60 cycles. The water-cooling chamber is especially designed to provide high cooling efficiency, where this requirement exists, without increasing the over-all water-pressure drop of the cooling jacket.

7189-A
PENTODE
FOR AF POWER AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 7189-A is a power-amplifier pentode designed for use in the audio-frequency power output stage of television and radio receivers and high-fidelity amplifiers.

The 7189-A is unilaterally interchangeable, both electrically and mechanically, with the 7189. It differs from the 7189 in having a higher screen-voltage rating and in specifying the internal connections to pins 1 and 6.

MAXIMUM RATINGS

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

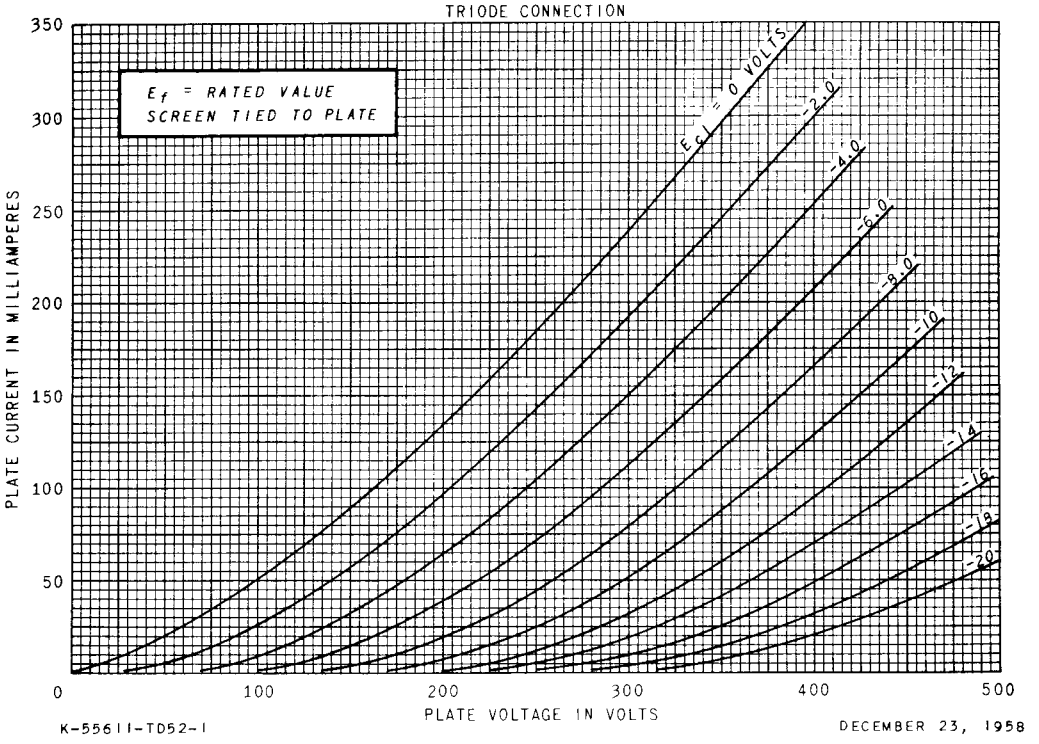
Effective Load Resistance, Plate-to-Plate	10000	10000	Ohms
Total Harmonic Distortion	2.5	2.5	Percent
Maximum-Signal Power Output	3.4	5.2	Watts

NOTES

* The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

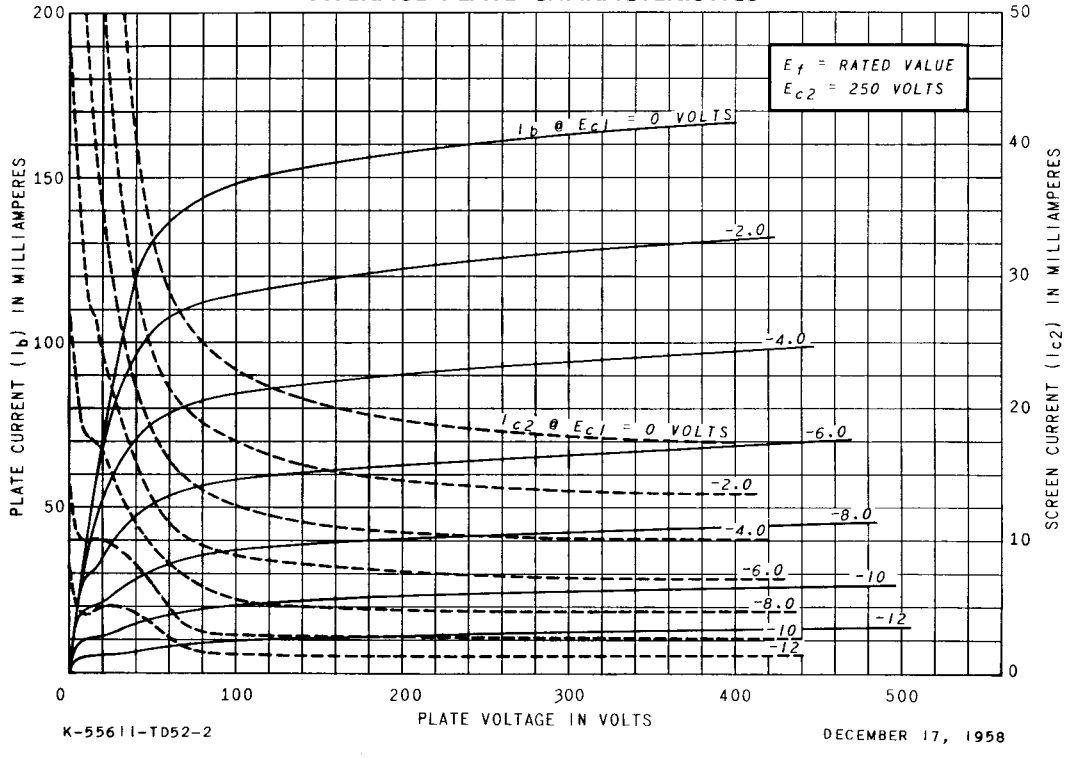
‡ Heater current of a bogey tube at Ef = 6.3 volts.

§ Without external shield.



¶ The Design-Maximum screen voltage rating is 415 volts in push-pull circuits where the screen of each tube is connected to a tap on the plate winding of the output transformer.

\# Screen dissipation may reach 4.4 watts during periods of maximum input of speech and music signals, under worst probable operating conditions as specified for the Design-Maximum rating system.



△ With screen tied to plate.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

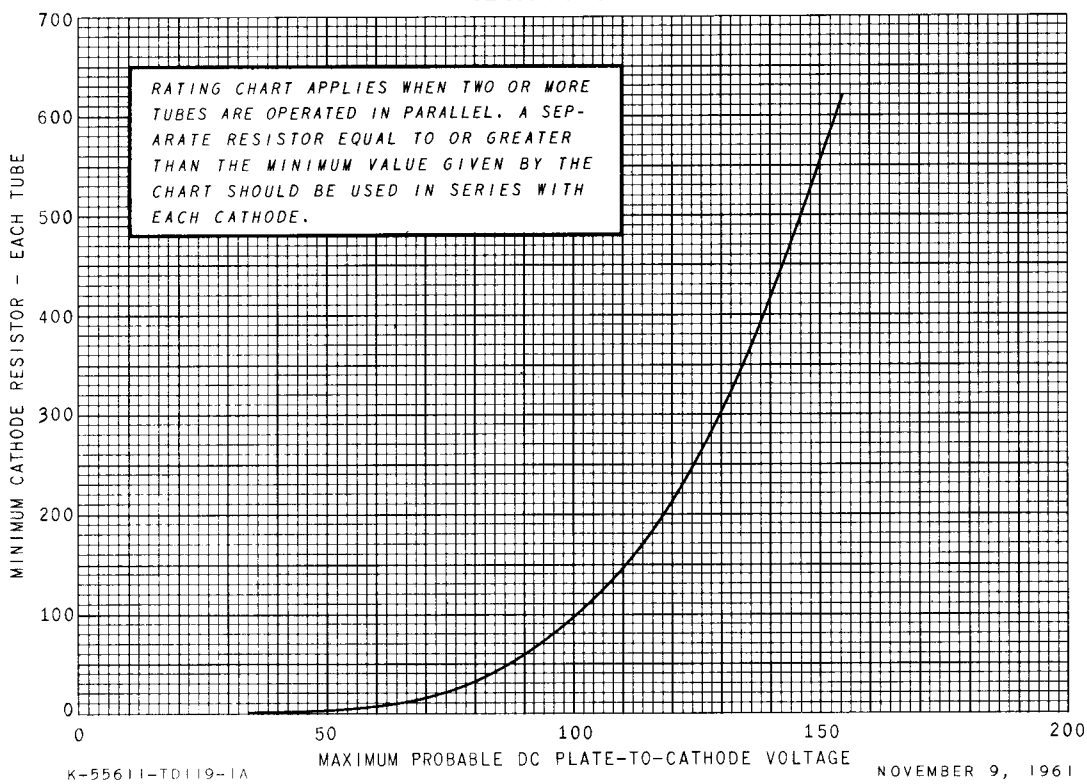
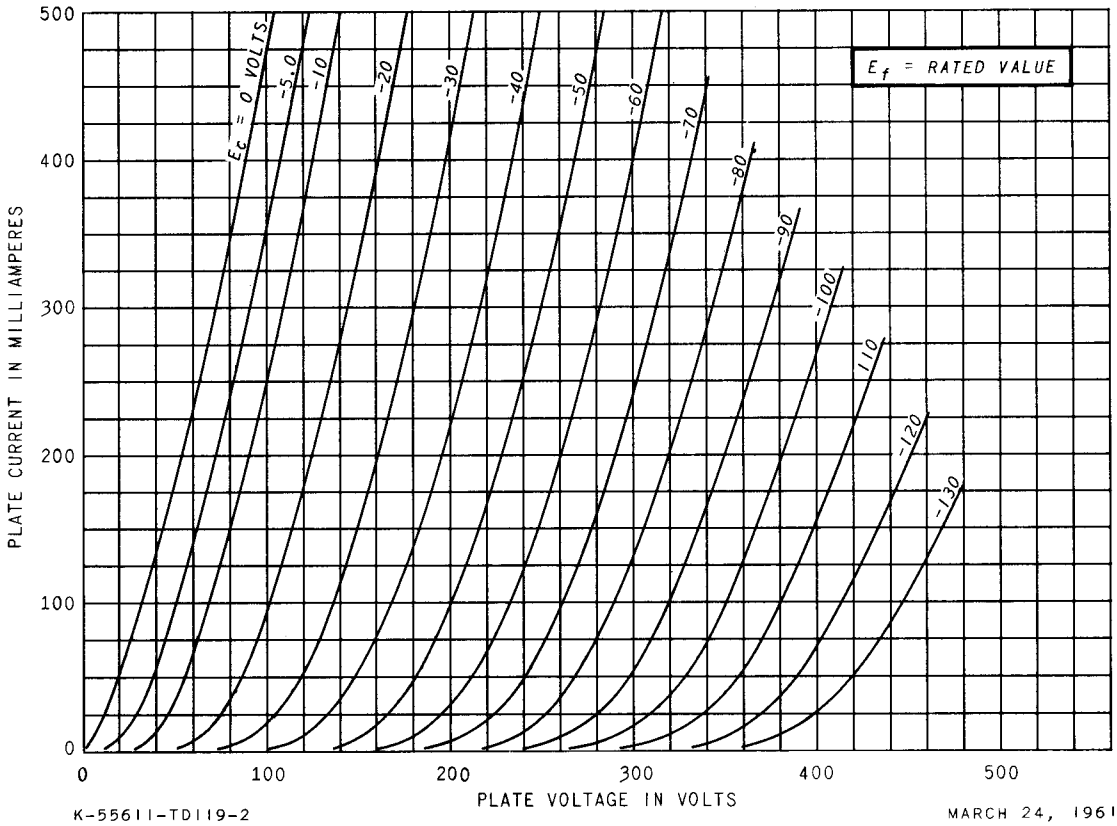
§ The use of fixed bias is not recommended when two or more tubes are used in parallel.



Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.



The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

DOUBLE TRIODE

DESCRIPTION AND RATING

The 7247 is a dissimilar double-triode designed for use in high-fidelity audio amplifiers. Section 1, which is similar to one section of a 7025, is intended for application in low-level, high-gain stages where low hum and microphonism are desired. Section 2, which is similar to one section of a 12AU7, is intended for cathode follower or phase-inverter service.

METAL-CERAMIC DIODE

DESCRIPTION AND RATING

The 7266 is a cathode-type diode of ceramic-and-metal planar construction. It is intended for detector, high-frequency instrument probe, and low-current rectifier applications. The 7266 is especially suited for use where unfavorable conditions of mechanical shock, mechanical vibration, and nuclear radiation are encountered.

SPECIAL PERFORMANCE TESTS

Low Pressure Voltage Breakdown Test
Statistical sample tested for voltage breakdown at a pressure of 8mm Hg, to simulate an altitude of 100000 feet. Tubes shall not give visual evidence of flashover or corona when 300 volts RMS, 60 cps, is applied between the plate and cathode terminals.

DEGRADATION RATE TESTS

Fatigue

Statistical sample vibrated for a total of six hours, three hours in each of two planes, at a peak acceleration of 10G. Frequency is continuously varied from 30 cps to 2000 cps and back to 30 cps, with a period of ten minutes. Tubes are operated during the test with Ef = 6.3 volts and Ehk = +100 volts. Following the test, tubes are evaluated for heater-cathode leakage and heater current.

Shock

Statistical sample subjected to 5 impact accelerations of approximately 450G in each of four positions. The accelerating forces are applied by the Navy-type, High Impact (flyweight) Shock Machine using a 30° hammer angle. Tubes are operated during the test with Ef = 6.3 volts and Ehk = +100 volts. Following the test, tubes are evaluated for heater-cathode leakage and heater current.

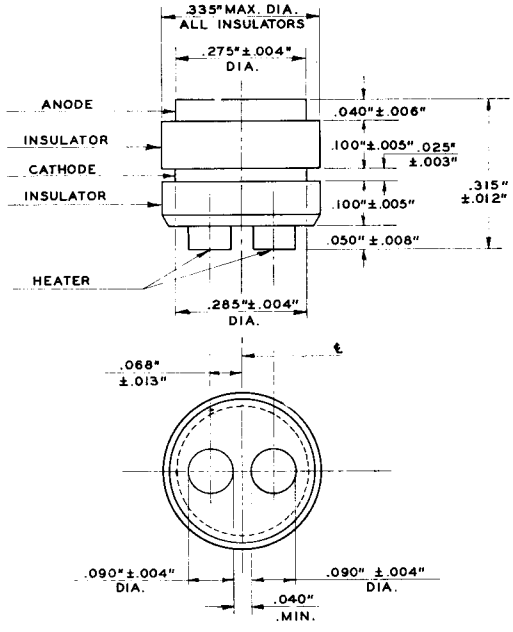
Survival Rate Life Test

The combined statistical samples subjected to the Intermittent and Standby Life Tests are evaluated for shorted and open elements and tube voltage drop following approximately 100 hours of life test.

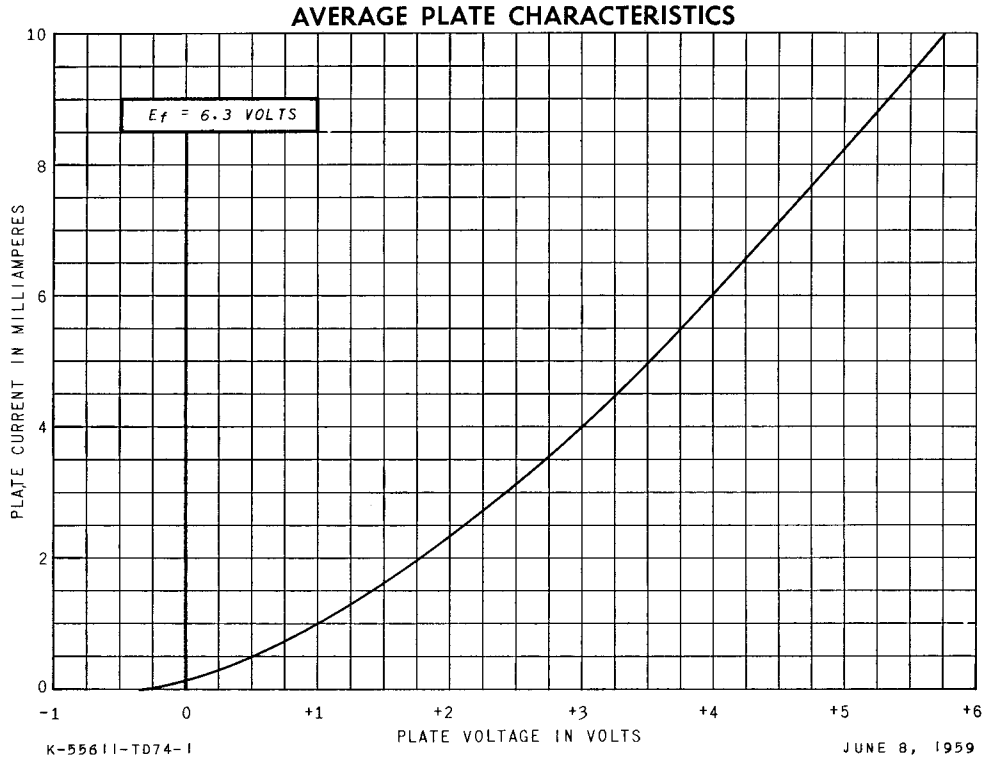
Intermittent Life Test

Statistical sample operated for 1000 hours under the following conditions: Ef = 6.3 volts (cycled—on 1¾ hours, off ¼ hour), Ebb = 220 volts RMS, Ehk = −70 volts d-c, R_L = 0.13 meg, C_L = 1.0 μf, and Rs = 1300 ohms. Tubes are evaluated, following 500 and 1000 hours of life test, for shorted or open elements, heater current, tube voltage drop, heater-cathode leakage, interelectrode leakage resistance, and emission.

Standby Life Test



Statistical sample operated for 1000 hours under the following conditions: Ef = 6.3 volts (cycled—on 1¾ hours, off ¼ hour) no other voltages applied. Tubes are evaluated, following 500 and 1000 hours of life test, for shorted or open elements, heater current, tube voltage drop, heater-cathode leakage, interelectrode leakage resistance, and emission.



Heater-Cycling Life Test

Statistical sample operated for 2000 cycles minimum to evaluate and control heater-cathode defects. Conditions of test include Ef = 7.0 volts cycled for one minute on and one minute off, Eb = 0 volts, and Ehk = 70 volts with heater positive with respect to cathode. Following this test, tubes are evaluated for open heaters, heater-cathode shorts, and heater-cathode leakage current.

Note: The conditions for some of the indicated tests have deliberately been selected to aggravate tube failures for test and evaluation purposes. In no sense should these conditions be interpreted as suitable operating conditions.

PLANAR TRIODE

DESCRIPTION AND RATING

FOR GROUNDED-GRID OSCILLATOR, AMPLIFIER, AND FREQUENCY MULTIPLIER SERVICE

Metal and Ceramic — Pulse Rated
High Transconductance — Shock Resistant
100 Watts Plate Dissipation

The 7289 is a metal-and-ceramic, high-mu triode designed for use as a grounded-grid CW oscillator, amplifier, or frequency multiplier at frequencies as high as 2500 megacycles. In addition, it may be used as a plate-pulsed oscillator or amplifier at frequencies as high as 3000 megacycles.

Features of the 7289 include planar electrode construction, high plate dissipation capability, excellent electrode isolation, low radio-frequency losses, high transconductance, and low interelectrode capacitances.

* The equipment designer should design the equipment so that heater voltage is centered at some value within the range of 4.5 to 5.7 volts for CW operation, or 5.7 to 6.0 volts for pulse operation. Heater voltage variations about the center value should be kept as small as practical and should not, in any case, exceed ±5%. The optimum center value of heater voltage depends on the cathode current and on other parameters of circuit design and operation. For specific recommendations, contact your General Electric tube sales representative.

† Heater current of a bogey tube at Ef = 6.0 volts.

‡ Measured in a special shielded socket.

§ Modulation essentially negative may be used if the positive peak of the audio-frequency envelope does not exceed 115% of the carrier conditions.

¶ For modulation factors less than 1.0, a higher d-c plate voltage may be used if the sum of the peak positive audio voltage and the d-c plate voltage does not exceed 1200 volts.

⁂ Applications with a duty factor greater than 0.0025 should be referred to your General Electric tube sales representative for recommendations.

△ In any 5000-microsecond interval.

** The regulation and/or series plate-supply impedance must be such as to limit the peak current, with the tube considered a short circuit, to a maximum of 30 amperes.

†† The maximum instantaneous value should be within the range of +250 to −750 volts.

§§ Adjusted for Ib = 70 milliamperes.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

NOTES

1. The total indicated runout of the plate contact surface with respect to the cathode contact surfaces will not exceed .020 inch.
2. The total indicated runout of the cathode contact surface with respect to the heater contact surfaces will not exceed .012 inch.
3. The total indicated runout of the grid contact surface with respect to the cathode contact surface will not exceed .020 inch.
4. Do not clamp or locate on this surface.
5. Hole provided for tube extractor through the top fin only.
6. Measure plate shank temperature on this surface.

7296

METAL-CERAMIC TRIODE

DESCRIPTION AND RATING

FOR VHF OSCILLATOR AND AMPLIFIER APPLICATIONS

The 7296 is a high-mu triode of ceramic-and-metal planar construction primarily intended for use as an oscillator, broadband radio-frequency amplifier, or VHF power amplifier. The 7296 is especially suited for use where unfavorable conditions of mechanical shock, mechanical vibration, and nuclear radiation are encountered.

GENERAL

MAXIMUM RATINGS

ABSOLUTE-MAXIMUM VALUES

Plate Voltage	330	Volts
Positive DC Grid Voltage	0	Volts
Negative DC Grid Voltage	50	Volts
Plate Dissipation	5.5	Watts
DC Grid Current	10	Milliamperes
DC Cathode Current	30	Milliamperes
Peak Cathode Current	120	Milliamperes
Heater-Cathode Voltage		
Heater Positive with Respect to Cathode	50	Volts
Heater Negative with Respect to Cathode	50	Volts
Grid Circuit Resistance		
With Fixed Bias	0.1	Megohms
With Cathode Bias	0.18	Megohms
Envelope Temperature at Hottest Point ※		
Plate Dissipation not over 3.3 Watts	300	C
Plate Dissipation up to 5.5 Watts	250	C

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

CHARACTERISTICS AND TYPICAL OPERATION

AVERAGE CHARACTERISTICS

Plate Voltage	200	Volts
Cathode-Bias Resistor	68	Ohms
Amplification Factor	90	
Plate Resistance, approximate	5450	Ohms
Transconductance	16500	Micromhos
Plate Current	17	Milliamperes
Grid Voltage, approximate Ib = 10 Microamperes	−5.5	Volts

* The equipment designer should design the equipment so that the heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

† Heater current of a bogey tube at Ef = 6.3 volts.

‡ Without external shield.

§ One method of mounting the 7296 is to use a stainless-steel "T" bolt (see drawing) to attach the mounting base of the tube to a chassis or circuit board. The "T" bolt should be inserted in the slot in the base of the tube, turned 90 degrees, and attached to the chassis or circuit board with a 4-40 nut and lock washer. Torque used to tighten the nut should not exceed 3 inch-pounds.

⁂ Operation below the rated maximum envelope temperatures is recommended for applications requiring the longest possible tube life. The 7296 is also capable of operation at envelope temperatures much higher than the rated maximum values. For specific recommendations concerning higher temperature operation, contact your General Electric tube sales representative.

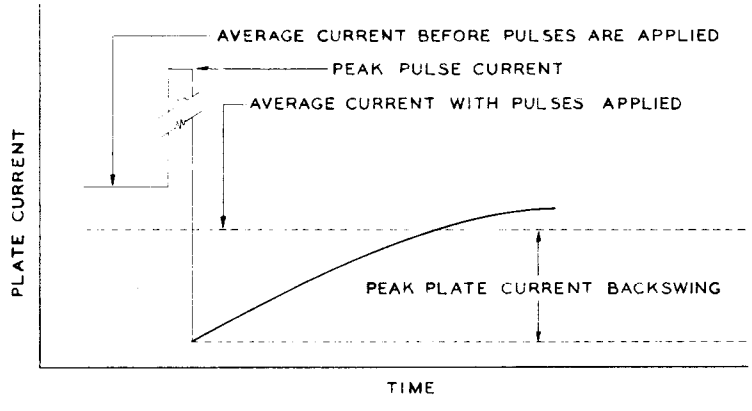
INITIAL CHARACTERISTICS LIMITS

	Min.	Bogey	Max.	
Heater Current				
Ef = 6.3 volts	370	400	430	Milliamperes
Plate Current				
Ef = 6.3 volts, Eb = 200 volts, Rk = 68 ohms (bypassed)	10	17	24	Milliamperes
Transconductance				
Ef = 6.3 volts, Eb = 200 volts, Rk = 68 ohms (bypassed)	13000	16500	20000	Micromhos
Amplification Factor				
Ef = 6.3 volts, Eb = 100 volts, Rk = 68 ohms (bypassed)	65	90	115	
Zero-Bias Transconductance				
Ef = 6.3 volts, Eb = 100 volts, Ec = 0 volts	13000	20000	.....	Micromhos
Grid Voltage Cutoff				
Ef = 6.3 volts, Eb = 200 volts, Ib = 10 μa	.....	−5.5	−9.5	Volts
Interelectrode Capacitances				
Grid to Plate (g to p)	1.9	2.2	2.5	pf
Input: g to (h + k)	3.7	5.0	6.3	pf
Output: p to (h + k)	0.05	0.075	0.1	pf
Heater to Cathode: (h to k)	2.1	2.8	3.5	pf
Negative Grid Current				
Ef = 6.3 volts, Eb = 200 volts, Ecc = −1.0 volts, Rk = 68 ohms (bypassed), Rg = 0.18 meg	.....	.....	0.5	Microamperes
Heater-Cathode Leakage Current				
Ef = 6.3 volts, Ehk = 100 volts				
Heater Positive with Respect to Cathode	.....	.....	20	Microamperes
Heater Negative with Respect to Cathode	.....	.....	20	Microamperes
Interelectrode Leakage Resistance				
Ef = 6.3 volts. Polarity of applied d-c interelectrode voltage is such that no cathode emission results.				
Grid to All at 100 volts d-c	100	.....	.....	Megohms
Plate to All at 300 volts d-c	100	.....	.....	Megohms
Grid Emission Current				
Ef = 7.0 volts, Eb = 200 volts, Ecc = −15 volts, Rg = 0.18 meg	.....	.....	2.0	Microamperes

SPECIAL PERFORMANCE TESTS

	Min.	Bogey	Max.	
400 Megacycle Oscillator Power Output	1.6	2.0	.....	Watts

Tubes are tested for power output as an oscillator under the following conditions: F = 400 mc, Ef = 6.3 volts, Eb = 300 volts, Rg = 1400 ohms, Ib = 20 ma maximum, Ic = 6.0–9.0 ma.



Pulse Emission	320	.....	.....	Milliamperes

Tubes are tested for pulse emission under the following conditions: Ef = 6.3 volts, Eb = 200 volts, Ec = −20 volts, egk = +12 volts, prr = 1000 pps, duty cycle 1%. Pulse cathode current is measured.

Grid Recovery — Change in Average Plate Current	.....	.....	1.0	Milliamperes
Peak Plate Current Backswing	.....	.....	2.0	Milliamperes

Tubes with poor grid recovery affect circuit operation, when the grid is driven positive by a pulse of signal or noise, somewhat as if a parallel RC circuit were in series with the grid. This effect may occur in tubes of any type, but is unimportant in many applications. In the majority of 7296 tubes the effect is negligible, but to eliminate the few in which it may be excessive, tubes are tested under the following conditions: Ef = 6.3 volts, Ebb = 250 volts, R_L = 0.01 meg. Ec is adjusted for Ib = 10 ma.

Upon application to the grid of a pulse driving it 3 volts positive with respect to cathode (prr = 60 pps, duty cycle = 0.12%) the change in average plate current is noted, and the peak plate current backswing is measured. The following diagram shows qualitatively the plate current—time relationship for a tube (with poor grid recovery) subjected to this test:

Low Frequency Vibrational Output	.....	.....	15	Millivolts RMS

Statistical sample is subjected to vibration in each of two planes at 40 cps, with peak acceleration 15 G. Tube is operated with Ef = 6.3 volts, Ebb = 200 volts, Rk = 68 ohms (bypassed), R_L = 2000 ohms.

Variable Frequency Vibrational Output

The tube is designed to be free of vibrational outputs in excess of 100 mv RMS at any frequency within the range 100–2000 cps, when vibrated in either of two planes at 10 G peak acceleration. Electrical conditions for this test are the same as for Low Frequency Vibrational Output.

Low Pressure Voltage Breakdown Test

Statistical sample tested for voltage breakdown at a pressure of 8 mm Hg, to simulate an altitude of 100,000 feet. Tubes shall not give visual evidence of flashover or corona when 300 volts RMS, 60 cps, is applied between the plate and grid terminals.

DEGRADATION RATE TESTS

Fatigue

Statistical sample vibrated for a total of six hours, three hours in each of two planes, at a peak acceleration of 10 G. Frequency is continuously varied from 30 cps to 2000 cps and back to 30 cps, with a period of ten minutes. Tubes are operated during the test with Ef = 6.3 volts, Eb = 200 volts, and Rk = 68 ohms. Following the test, tubes are evaluated for low frequency vibrational output, heater-cathode leakage, heater current, and transconductance.

Shock

Statistical sample subjected to 5 impact accelerations of approximately 600 G in each of four positions. The accelerating forces are applied by the Navy-type, High Impact (flyweight) Shock Machine using a 42° hammer angle. Tubes are mounted by T-bolt with 3 inch-pounds torque, and operated during the test with Ef = 6.3 volts, Eb = 200 volts, Ehk = +100 volts, Rg = 0.1 Meg, and Rk = 68 ohms. Following the test, tubes are evaluated for low frequency vibrational output, heater-cathode leakage, heater current, and transconductance.

Stability Life Test

The statistical sample subjected to the Dynamic Life Test is evaluated for percent change in zero-bias transconductance of individual tubes, from the initial reading to readings following 2 hours and 20 hours of the life test.

Survival Rate Life Test

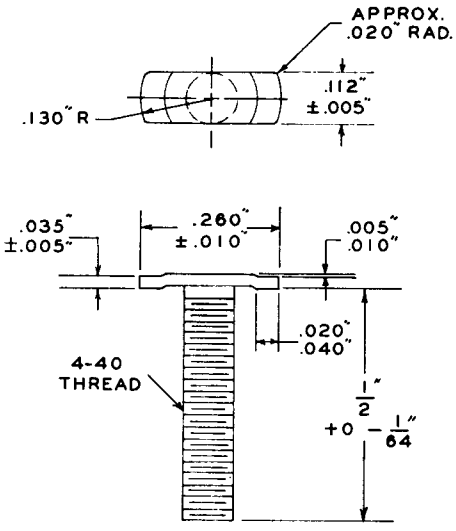
The combined statistical samples subjected to the Dynamic and Pulse Life Tests are evaluated for shorted and open elements following approximately 100 hours of life test.

Dynamic Life Test

Statistical sample operated, with a 60 cps grid signal, at maximum rated DC grid current and cathode current for a period of 1000 hours. Heater voltage is cycled (on 1¾ hours, off ¼ hour). Tubes are evaluated, following 500 and 1000 hours of life test, for shorted or open elements, heater current, zero-bias transconductance, oscillator power output, and heater-cathode leakage.

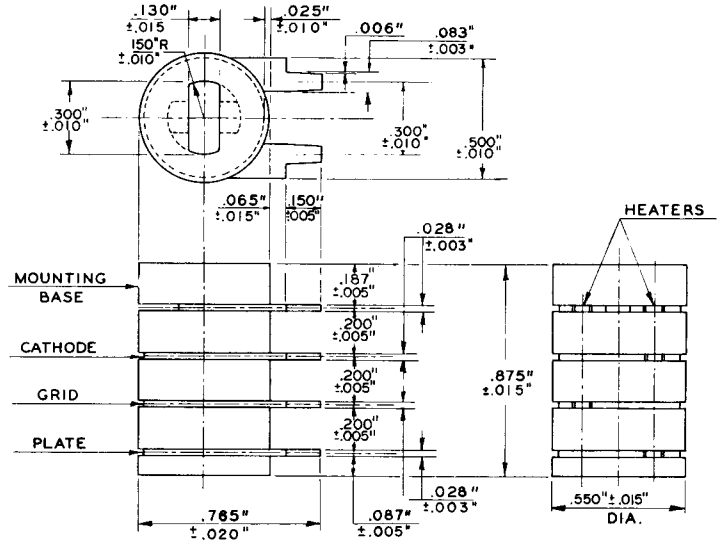
Pulse Life Test

Statistical sample operated with 400 ma peak cathode current, 1% duty cycle, for 1000 hours. Heater voltage is cycled (on 1¾ hours, off ¼ hour). Tubes are evaluated, following 500 and 1000 hours of life test, for shorted or open elements, heater current, pulse emission, and heater-cathode leakage.



Interface Life Test

Statistical sample operated for 1000 hours with Ef = 6.6 volts, no other voltages applied, and evaluated for cathode interface resistance following the life test.



Heater-Cycling Life Test

Statistical sample operated for 2000 cycles minimum to evaluate and control heater-cathode defects. Conditions of test include Ef = 7.5 volts cycled for one minute on and one minute off, Eb = Ec = 0 volts, and Ehk = 70 volts with heater positive with respect to cathode. Following this test tubes are evaluated for open heaters, heater-cathode shorts, and heater-cathode leakage current.

Planar Triode

7391

FOR GROUNDED-GRID CLASS C OSCILLATOR APPLICATIONS

The 7391 is a high-mu, metal-and-ceramic triode intended for operation as a grounded-grid, Class C oscillator at frequencies as high as 6000 megacycles.

Features of the tube include small size, planar electrode construction with close spacing, inherent rigidity, and an envelope structure convenient for coaxial circuit applications.

The physical appearance and dimensions of the 7391 are identical to those of the 6299.

GL-7393

TRAVELING-WAVE TUBE

LESS THAN 10 DB NOISE FIGURE **4000-8000 MEGACYCLES**

25 DB GAIN **METAL-CERAMIC**

LOW NOISE

The GL-7393 is a ruggedized, low-noise, broadband traveling-wave tube for use in the 4000-to-8000-megacycle frequency range. It has a noise figure of less than 10 decibels across the entire band with a power output of five milliwatts.

The tube is of metal-and-ceramic construction and is supplied as a complete packaged assembly which includes the focusing magnets, connectors, and housing. The entire assembly weighs approximately 11.5 pounds.

The broad bandwidth, low-noise, high gain, freedom from tuning adjustments, and rugged construction make this tube particularly useful in military systems. As the input tube for radar receivers, it has the decided advantages of low noise and protection to the crystal mixer. Other applications include electronic countermeasures equipment, microwave relay systems, and radiometry.

Electrical

Frequency	4000–8000	Megacycles
Heater		
Voltage	6.3	Volts
Current, nominal	0.3	Ampere
A heater-voltage regulation of ±2 percent is recommended to realize optimum gain and noise figure.

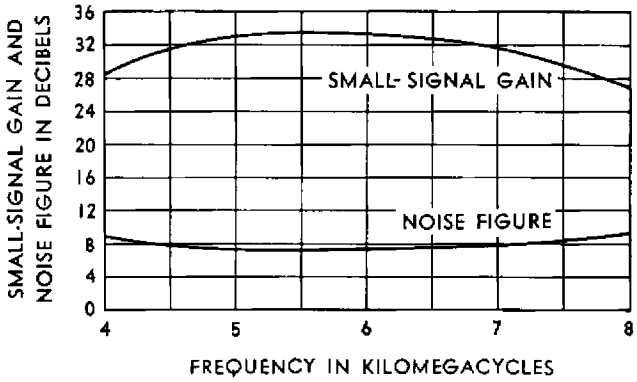
*Over band with the same operating voltages that provide minimum gain variation.

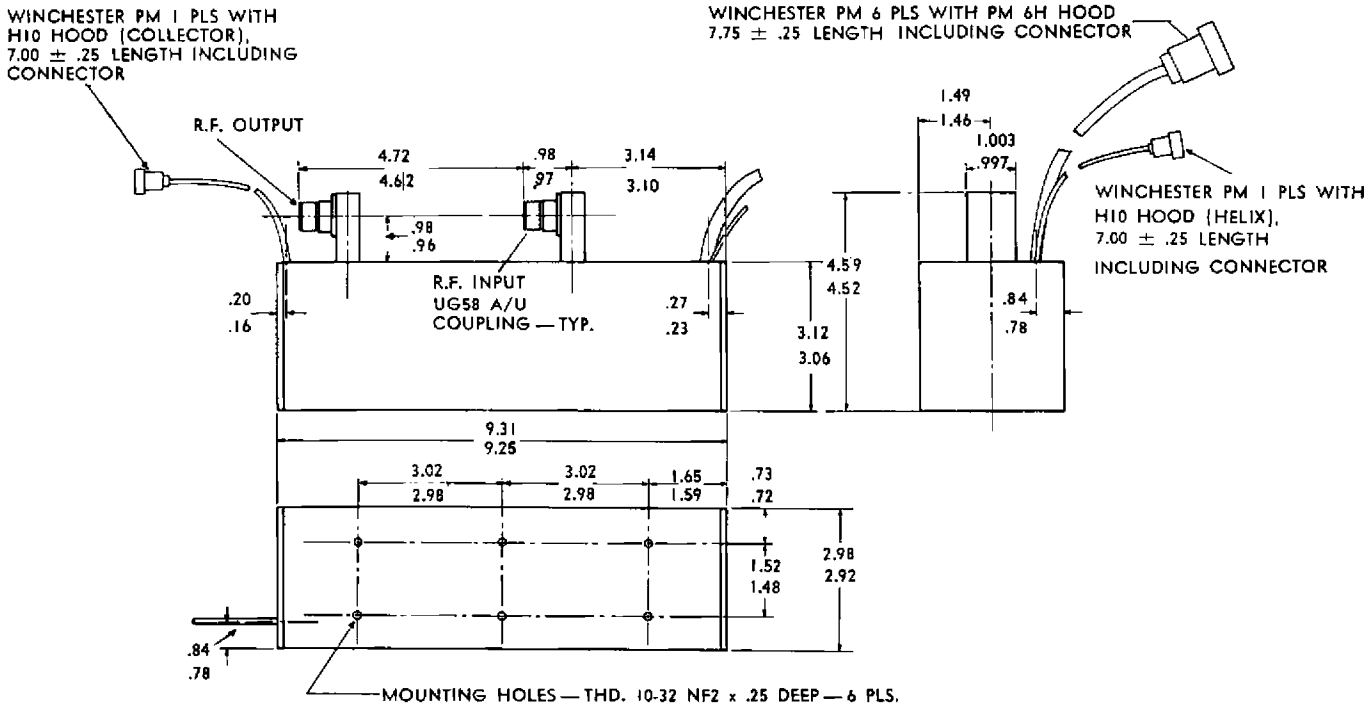
**All voltages may be isolated from ground; i.e., it is not necessary to operate the cathode, helix, collector, or any other electrode at ground potential. Voltages shown are measured with respect to cathode. For minimum noise and optimum gain characteristics, voltages should be adjusted to values specified by instructions accompanying each tube.

PERFORMANCE ASSURANCE SPECIFICATIONS

Shock (energized)	30 G for 11 milliseconds on each of three mutually perpendicular axes.
Vibration (operating)	0.031 inches double amplitude from 5 to 55 cycles per second and 5 G from 55 to 1500 cycles per second with sweep over 5 to 1500 cycles per second for 100 minutes on each of three mutually perpendicular axes.
Humidity (non-operating)	MIL-E-5272 C, Paragraph 4.4.1 (Procedure I); i.e., non-operating tube in 95 percent relative humidity atmosphere for 10 days with temperature cycled slowly from approximately 30 C to 71 C each day.
Acoustic noise (operating)	135 decibels, 25 to 12,000 cycles per second random noise.



PERMANENT-MAGNET PRECAUTIONS



This tube uses a uniform-field permanent magnet as the focusing structure. A label on the tube specifies a nominal lower limit of two inches on magnetic-material proximity. It must be realized that strong external magnets or large amounts of magnetic material at this distance may permanently damage the tube. A small screwdriver will not, while a large a-c transformer or a large sheet of steel at this distance may cause damage by defocusing the tube.

In addition, a related caution is important and must be remembered whenever handling a uniform-field tube. The permanent magnets of these tubes cause a large attractive force between the tube and magnetic material. Unless one is always careful to hold the tube and/or magnetic objects near the tube firmly, the result is sudden direct contact. The magnetic object may cause tube damage due to violations of the minimum spacing requirement.

For small steel hand tools, a two-inch limit is sufficient. For large magnetic objects with magnetic fields of their own, the lower minimum distance should be determined accurately by testing. To accomplish this, the tube may be secured to a suitable three-foot-long dielectric support and the tube case grounded. With the tube operating and its helix current being measured, the tube may be moved slowly by the dielectric support toward the magnetic object. (CAUTION: Appropriate electrical safety procedures should be followed at all times.) The minimum distance for which there is no degradation in r-f performance is the point at which the helix current starts to increase. If a slight degradation in noise figure can be accepted, the helix current may be allowed to increase somewhat as long as it stays below its operating maximum.

TRAVELING-WAVE TUBE

LESS THAN 10 DB NOISE FIGURE **8000-12,000 MEGACYCLES**

25 DB GAIN **METAL-CERAMIC**

LOW NOISE

The GL-7394 is a ruggedized, low-noise, broadband traveling-wave tube for use in the 8000-to-12,000 megacycle frequency range. It has a noise figure of less than 10 decibels across the entire band with a power output of 5 milliwatts.

The tube is of metal-and-ceramic construction and is supplied as a complete packaged assembly which includes permanent focusing magnets, connectors, and housing. The entire assembly weighs approximately 11.5 pounds.

The broad bandwidth, low-noise, high gain, freedom from tuning adjustments, and rugged construction make this tube particularly useful in military systems. As the input tube for radar receivers, it has the decided advantages of low noise and protection to the crystal mixer. Other applications include electronic countermeasures equipment, microwave relay systems, and radiometry.

PACKAGED VOLTAGE-TUNABLE MAGNETRON

2200-3850 MEGACYCLES **2 WATTS CW OUTPUT**

The GL-7398 is a packaged voltage-tunable magnetron designed for voltage-tunable operation in the 2200 to 3850-megacycle frequency range. It is a complete r-f power source package requiring only input power connections and an r-f power output connection and has a minimum CW power output of two watts across the entire frequency range. The tube may be voltage-tuned over a portion or all of the frequency range for which it is designed or operated at a fixed frequency. The voltage-frequency relationship is essentially linear.

FORCED-AIR COOLED
METAL AND CERAMIC

INTEGRAL RADIATOR

The GL-7399 is a small-size, four-electrode transmitting tube especially designed for pulsed-amplifier or -oscillator service at L-band frequencies. This tetrode is particularly well suited for use in airborne or ground-based radar equipment.

The tube is capable of providing useful output at frequencies up to approximately 1500 megacycles.

Features of the GL-7399 include long life and reliability, long pulse width, high peak power and high gain, broad-banding capability, and resistance to shock and vibration.

These together with such design factors as an oxide-coated cathode, coaxial elements, and metal-ceramic construction make the tube well adapted to application in modern systems where performance and reliability are important.

SPECIAL PERFORMANCE TESTS

Low Frequency Vibrational Output				
Statistical sample is subjected to vibration in each of two planes at 40 cps, with peak acceleration 15 G. Tube is operated with Ef = 6.3 volts, Ebb = 150 volts, Rk = 82 ohms (bypassed), R_L = 10000 ohms	.....	.....	10	Millivolts RMS
Variable Frequency Vibrational Output				
Statistical sample is subjected to vibration according to the procedure given below. Tube is operated with Ef = 6.3 volts, Ebb = 150 volts, Rk = 82 ohms (bypassed) R_L = 10000 ohms	.....	.....	15	Millivolts RMS

The variable-frequency vibration test shall be performed as follows:

1. The frequency shall be increased from 100 to 2000 cps with approximately logarithmic progression in 3 ± 1 minutes. The return sweep (2000 to 100 cps) is not required.
2. The tube shall be vibrated with simple harmonic motion in each of two planes: first, parallel to the cylindrical axis; second, perpendicular to the cylindrical axis and parallel to a line through the major axis of a terminal lug. At all frequencies from 100 to 2000 cps, the total harmonic distortion of the acceleration waveform shall be less than 5%.
3. The peak acceleration shall be maintained at 10 ± 1.0 G throughout the test.
4. The value of the alternating voltage produced across the load resistor (R_L), as a result of the vibration, shall be measured with a suitable device having a response to the RMS value of the voltage to within ±0.5 db of the response at 400 cps for the frequency range of 100 to 3000 cps, and having a band-pass filter with an attenuation rate of 24 db per octave below the low frequency cutoff point of 50 cps and above the high frequency cutoff point of 5000 cps. The meter shall have a dynamic response characteristic equivalent to or faster than a VU meter (operated in accordance with ASA Standard No. C16.5-1954).

Low Pressure Voltage Breakdown Test
Statistical sample tested for voltage breakdown at a pressure of 8 mm Hg, to simulate an altitude of 100,000 feet. Tubes shall not give visual evidence of flashover or corona when 300 volts RMS, 60 cps, is applied between the plate and grid terminals.

DEGRADATION RATE TESTS

Fatigue

Statistical sample vibrated for a total of six hours, three hours in each of two planes, at a peak acceleration of 10 G. Frequency is continuously varied from 30 cps to 2000 cps and back to 30 cps, with a period of ten minutes. Tubes are operated during the test with Ef = 6.3 volts, Eb = 150 volts, and Rk = 82 ohms. Following the test, tubes are evaluated for low frequency vibrational output, heater-cathode leakage, heater current, and transconductance.

Shock

Statistical sample subjected to 5 impact accelerations of approximately 450 G in each of four positions. The accelerating forces are applied by the Navy-type, High Impact (flyweight) Shock Machine using a 30° hammer angle. Tubes are operated during the test with Ef = 6.3 volts, Eb = 150 volts, Ehk = +100 volts, Rg = 0.1 meg, and Rk = 82 ohms. Following the test, tubes are evaluated for low frequency vibrational output, heater-cathode leakage, heater current, and transconductance.

Stability Life Test

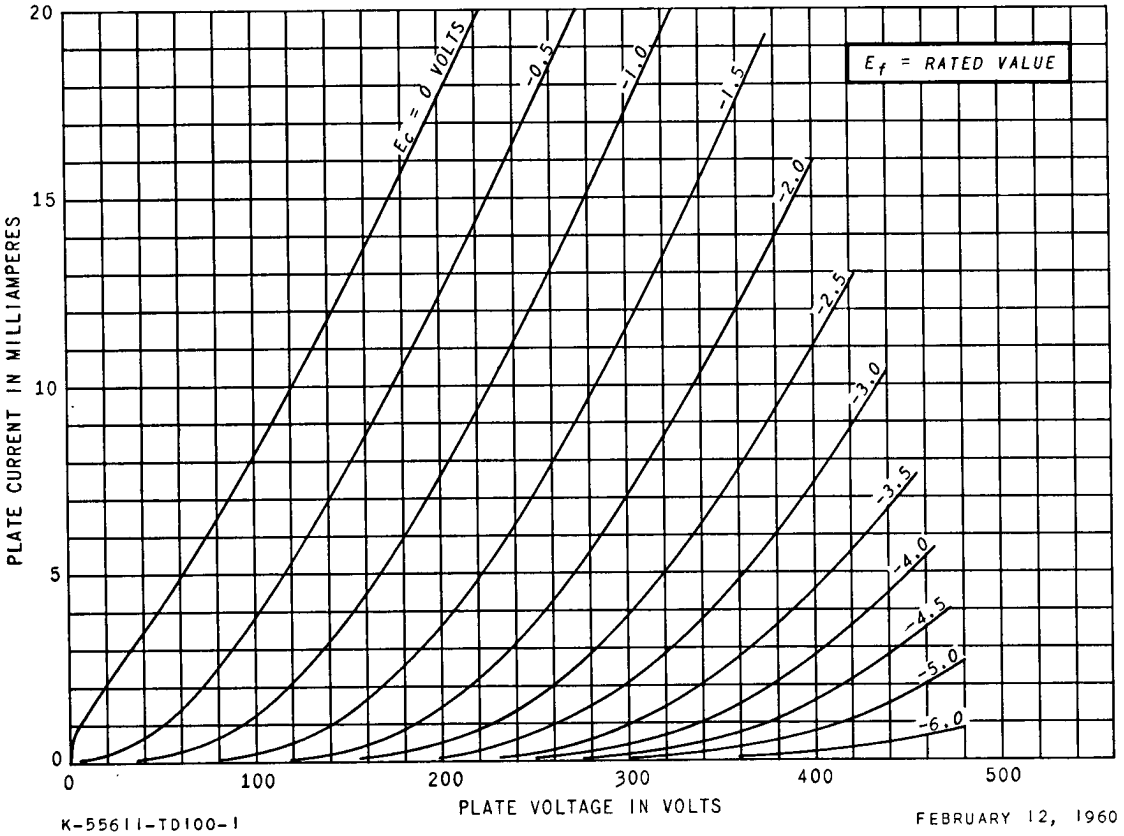
The statistical sample subjected to the Intermittent Life Test is evaluated for percent change in transconductance of individual tubes, from the initial reading to readings following 2 hours and 20 hours of the life test.

Survival Rate Life Test

The statistical sample subjected to the Intermittent Life Test is evaluated for shorted and open elements, and transconductance, following approximately 100 hours of life test.

Intermittent Life Test

Statistical sample operated 1000 hours under the following conditions: Ef = 6.3 volts, Eb = 150 volts, Ecc = +6 volts, Ehk = −70 volts, Rk = 910 ohms, Rg = 0.1 meg. Heater voltage is cycled (on 1¾ hours, off ¼ hour). Tubes are evaluated, following 500 and 1000 hours of life test, for shorted or open elements, heater current, transconductance, heater-cathode leakage, and interelectrode leakage resistance.



Interface Life Test

Statistical sample operated for 500 hours with Ef = 6.6 volts, no other voltages applied, and evaluated for cathode interface resistance following the life test.

Heater-Cycling Life Test

Statistical sample operated for 2000 cycles minimum to evaluate and control heater-cathode defects. Conditions of test include Ef = 7.0 volts cycled for one minute on and one minute off, Eb = Ec = 0 volts, and Ehk = 70 volts with heater positive with respect to cathode. Following the test, tubes are evaluated for open heaters, heater-cathode shorts, and heater-cathode leakage.

7486

METAL-CERAMIC TRIODE

FOR UHF OSCILLATOR AND POWER AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 7486 is a high-mu triode of ceramic-and-metal planar construction intended for use as an oscillator or radio-frequency power amplifier in the ultra-high-frequency range. The 7486 is especially suited for use where unfavorable conditions of mechanical shock, mechanical vibration, and nuclear radiation are encountered.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

FOOTNOTES

* The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

† Heater current of a bogey tube at Ef = 6.3 volts.

‡ Measured using a grounded adapter that provides shielding between external terminals of tube.

§ Operation below the rated maximum envelope temperature is recommended for applications requiring the longest possible tube life. The 7486 is also capable of operation at envelope temperatures much higher than the rated maximum values. For specific recommendations concerning higher temperature operation, contact your General Electric tube sales representative.

SPECIAL PERFORMANCE TESTS

	Min.	Bogey	Max.	
1200 Megacycle Oscillator Power Output	200	.....	.....	Milliwatts

Tubes are tested for power output as an oscillator under the following conditions: F = 1200 mc ± 50 mc, Ef = 6.3 volts, Eb = 150 volts, Rg = 1000 ohms, Ib = 8.0 ma maximum, Ic = 1.6 − 2.0 ma

Pulse Emission	90	.....	.....	Milliamperes

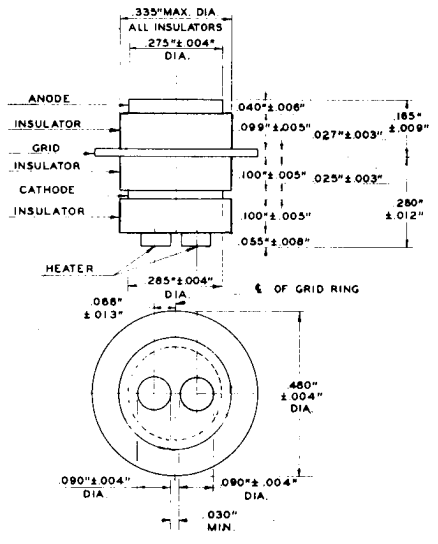
Tubes are tested for pulse emission under the following conditions: Ef = 6.3 volts, Eb = 150 volts, Ec = −10 volts, egk = +7 V, prr = 1000 pps, duty factor = 0.01. Pulse cathode current is measured

Grid Recovery				
Change in Average Plate Current	.....	.....	0.6	Milliamperes
Peak Plate Current Backswing	.....	.....	1.0	Milliamperes

Tubes with poor grid recovery affect circuit operation, when the grid is driven positive by a pulse of signal or noise, somewhat as if a parallel RC circuit were in series with the grid. This effect may occur in tubes of any type, but is unimportant in many applications. In the majority of 7486 tubes the effect is negligible, but to eliminate the few in which it may be excessive, tubes are tested under the following conditions: Ef = 6.3 volts, Ebb = 250 volts, R_L = 0.01 meg. Ec is adjusted for Ib = 3.0 ma.

Upon application to the grid of a 5-volt positive pulse (prr = 60 pps, duty factor = 0.0012) the change in average plate current is noted, and the peak plate current backswing is measured. The following diagram shows qualitatively the plate current-time relationship for a tube (with poor grid recovery) subjected to this test.

OUTLINE DRAWING



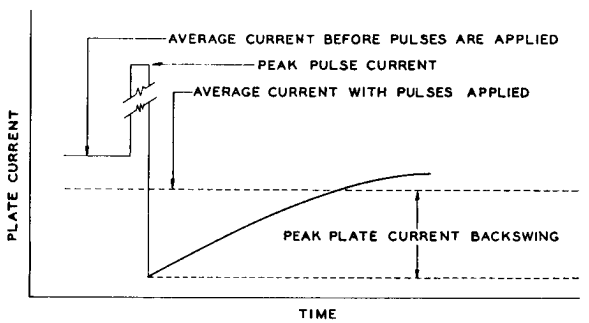


PLATE CURRENT VS TIME— GRID RECOVERY TEST

1—Maximum eccentricity of anode, grid, and cathode 0.005" from center line.

2—Maximum eccentricity of insulators 0.010" from center line.

3—Center line of grid ring used as reference line for horizontal tolerances.

4—Bottom surface of grid ring used as reference line for vertical tolerances.

SPECIAL PERFORMANCE TESTS (Continued)

	Min.	Bogey	Max.	
Low Frequency Vibrational Output				10 Millivolts RMS

Statistical sample is subjected to vibration in each of two planes at 40 cps, with peak acceleration 15G. Tube is operated with Ef = 6.3 volts, Ebb = 150 volts, Rk = 82 ohms (bypassed), R_L = 10000 ohms.

Variable Frequency Vibrational Output

The tube is designed to be free of vibrational outputs in excess of 15 mv RMS at any frequency within the range 100–2000 cps, when vibrated in either of two planes at 10G peak acceleration. Electrical conditions for this test are the same as for Low Frequency Vibrational Output.

Low Pressure Voltage Breakdown Test

Statistical sample tested for voltage breakdown at a pressure of 8 mm Hg, to simulate an altitude of 100,000 feet. Tubes shall not give visual evidence of flashover or corona when 300 volts RMS, 60 cps, is applied between the plate and grid terminals.

DEGRADATION RATE TESTS

Fatigue

Statistical sample vibrated for a total of six hours, three hours in each of two planes, at a peak acceleration of 10G. Frequency is continuously varied from 30 cps to 2000 cps and back to 30 cps, with a period of ten minutes. Tubes are operated during the test with Ef = 6.3 volts, Eb = 150 volts, and Rk = 82 ohms. Following the test, tubes are evaluated for low frequency vibrational output, heater-cathode leakage, and heater current.

Shock

Statistical sample subjected to 5 impact accelerations of approximately 450G in each of four positions. The accelerating forces are applied by the Navy-type, High Impact (flyweight) Shock Machine using a 30° hammer angle. Tubes are operated during the test with Ef = 6.3 volts, Eb = 150 volts, Ehk = +100 volts, and Rk = 82 ohms. Following the test, tubes are evaluated for low frequency vibrational output, heater-cathode leakage, and heater current.

Stability Life Test

The statistical sample subjected to the Dynamic Life Test is evaluated for percent change in zero-bias transconductance of individual tubes, from the initial reading to readings following 2 hours and 20 hours of the life test.

Survival Rate Life Test

The combined statistical samples subjected to the Dynamic and Pulse Life Tests are evaluated for shorted and open elements following approximately 100 hours of life test.

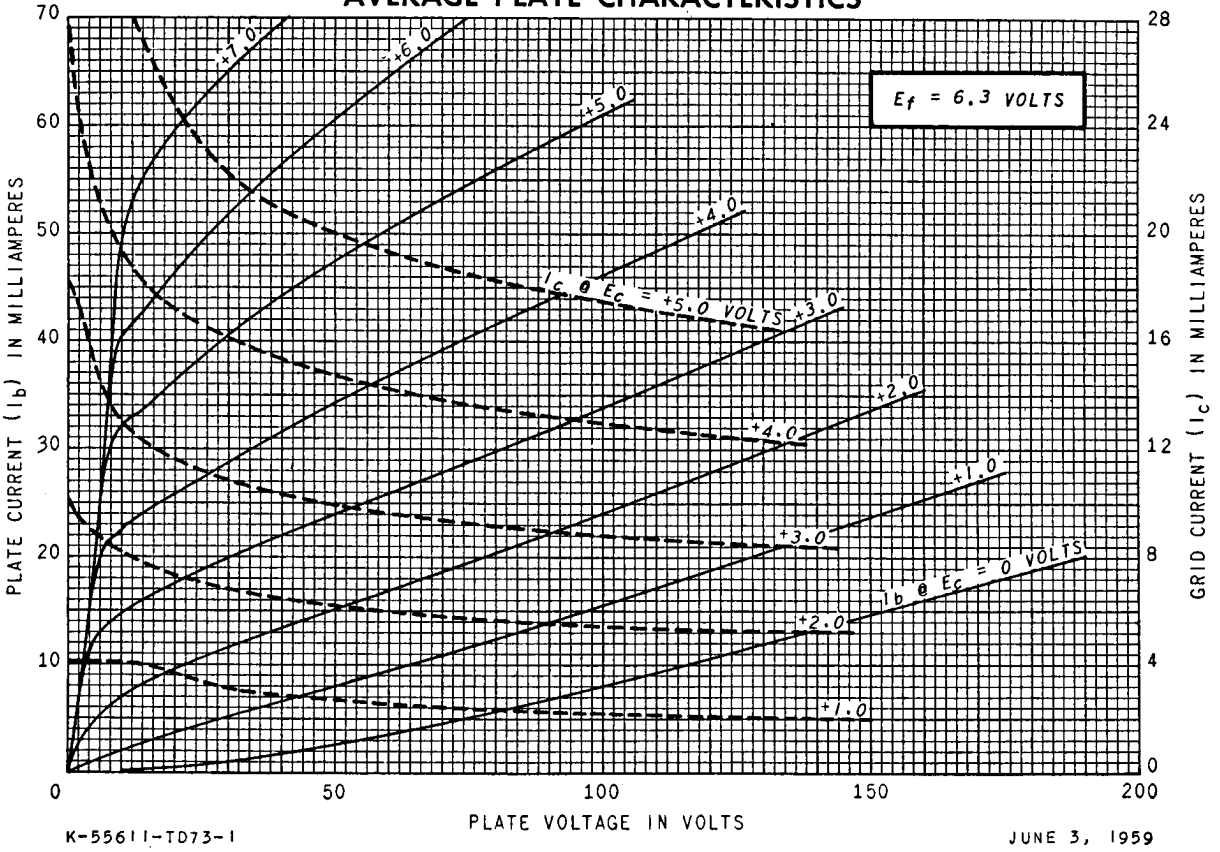
Dynamic Life Test

Statistical sample operated, with a 60 cps grid signal, at maximum rated DC grid current and cathode current for a period of 1000 hours. Heater voltage is cycled (on 1¾ hours, off ¼ hour). Tubes are evaluated, following 500 and 1000 hours of life test, for shorted or open elements, heater current, oscillator power output, zero-bias transconductance, heater-cathode leakage, and interelectrode leakage resistance.

Pulse Life Test

Statistical sample operated with 120 ma peak cathode current, 0.01 duty factor, for 1000 hours. Heater voltage is cycled (on 1¾ hours, off ¼ hour). Tubes are evaluated, following 500 and 1000 hours of life test, for shorted or open elements, heater current, pulse cathode current, heater-cathode leakage, and interelectrode leakage resistance.

Interface Life Test



Statistical sample operated for 1000 hours with Ef = 6.6 volts, no other voltages applied, and evaluated for cathode interface resistance following the life test.

Heater-Cycling Life Test

Statistical sample operated for 2000 cycles minimum to evaluate and control heater-cathode defects. Conditions of test include Ef = 7.0 volts cycled for one minute on and one minute off, Eb = Ec = 0 volts, and Ehk = 70 volts with heater positive with respect to cathode. Following this test, tubes are evaluated for open heaters, heater-cathode shorts, and heater-cathode leakage current.

Note: The conditions for some of the indicated tests have deliberately been selected to aggravate tube failures for test and evaluation purposes. In no sense should these conditions be interpreted as suitable circuit operating conditions.

SPECIAL PERFORMANCE TESTS

	Min.	Bogey	Max.	
Grid Recovery				
Change in Average Plate Current	....	....	1.0	Milliamperes
Peak Plate Current Backswing	....	....	2.0	Milliamperes

Tubes with poor grid recovery affect circuit operation when the grid is driven positive by a pulse of signal or noise, somewhat as if a parallel RC circuit were in series with the grid. This effect may occur in tubes of any type but is unimportant in many applications. In the majority of 7588 tubes the effect is negligible, but to eliminate the few in which it may be excessive, tubes are tested under the following conditions: Ef = 6.3 volts, Ebb = 250 volts, R_L = 0.01 meg. EC is adjusted for Ib = 10 ma.

Upon application to the grid of a pulse driving it 3 volts positive with respect to cathode (prr = 60 pps, duty cycle = 0.12%) the change in average plate current is noted, and the peak plate current backswing is measured. The following diagram shows qualitatively the plate current-time relationship for a tube (with poor grid recovery) subjected to this test:

PLATE CURRENT VS TIME —GRID RECOVERY TEST

	Min.	Bogey	Max.	
Low Frequency Vibrational Output Statistical sample is subjected to vibration in each of two planes at 40 cps, with peak acceleration 15G. Tube is operated with Ef = 6.3 volts, Ebb = 250 volts, Rk = 68 ohms (bypassed), R_L = 2000 ohms	....	.....	25	Millivolts RMS
Variable Frequency Vibrational Output Statistical sample is subjected to vibration according to the procedure given below. Tube is operated with Ef = 6.3 volts, Ebb = 250 volts, Rk = 68 ohms (bypassed), R_L = 2000 ohms	....	.....	75	Millivolts RMS

The variable-frequency vibration test shall be performed as follows:

1. The frequency shall be increased from 100 to 2000 cps with approximately logarithmic progression in 3 ± 1 minutes. The return sweep (2000 to 100 cps) is not required.
2. The tube shall be vibrated with simple harmonic motion in each of two planes: first, parallel to the cylindrical axis; second, perpendicular to the cylindrical axis and parallel to a line through the major axis of a terminal lug. At all frequencies from 100 to 2000 cps, the total harmonic distortion of the acceleration wave form shall be less than 5%.
3. The peak acceleration shall be maintained at 10 ± 1.0 G throughout the test.
4. The value of the alternating voltage produced across the load resistor (R_L), as a result of the vibration, shall be measured with a suitable device having a response to the RMS value of the voltage to within ±0.5 db of the response at 400 cps for the frequency range of 100 to 3000 cps, and having a band-pass filter with an attenuation rate of 24 db per octave below the low frequency cutoff point of 50 cps and above the high frequency cutoff point of 5000 cps. The meter shall have a dynamic response characteristic equivalent to or faster than a VU meter (operated in accordance with ASA Standard No. C16.5–1954).

Low Pressure Voltage Breakdown Test

Statistical sample tested for voltage breakdown at a pressure of 8mm Hg, to simulate an altitude of 100,000 feet. Tubes shall not give visual evidence of flashover or corona when 300 volts RMS, 60 cps, is applied between the plate and grid terminals.

DEGRADATION RATE TESTS

Fatigue

Statistical sample vibrated for a total of six hours, three hours in each of two planes, at a peak acceleration of 10 G. Frequency is continuously varied from 30 cps to 2000 cps and back to 30 cps, with a period of ten minutes. Tubes are operated during the test with Ef = 6.3 volts, Eb = 250 volts, and Rk = 68 ohms. Following the test, tubes are evaluated for low frequency vibrational output, heater-cathode leakage, heater current, and transconductance.

DEGRADATION RATE TESTS (Continued)

Shock

Statistical sample subjected to 5 impact accelerations of approximately 450 G in each of four positions. The accelerating forces are applied by the Navy-type, High Impact (flyweight) Shock Machine using a 30° hammer angle. Tubes are mounted by T-bolt with 3 inch-pounds torque, and operated during the test with Ef = 6.3 volts, Eb = 250 volts, Ehk = +100 volts, Rg = 0.1 meg, and Rk = 68 ohms. Following the test, tubes are evaluated for low frequency vibrational output, heater-cathode leakage, heater current, and transconductance.

Stability Life Test

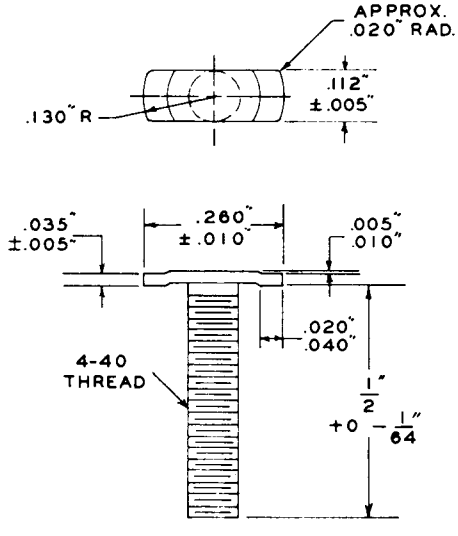
The statistical sample subjected to the Intermittent Life Test is evaluated for percent change in transconductance of individual tubes, from the initial reading to readings following 2 hours and 20 hours of the life test.

Survival Rate Life Test

The statistical sample subjected to the Intermittent Life Test is evaluated for shorted and open elements, and transconductance, following approximately 100 hours of life test.

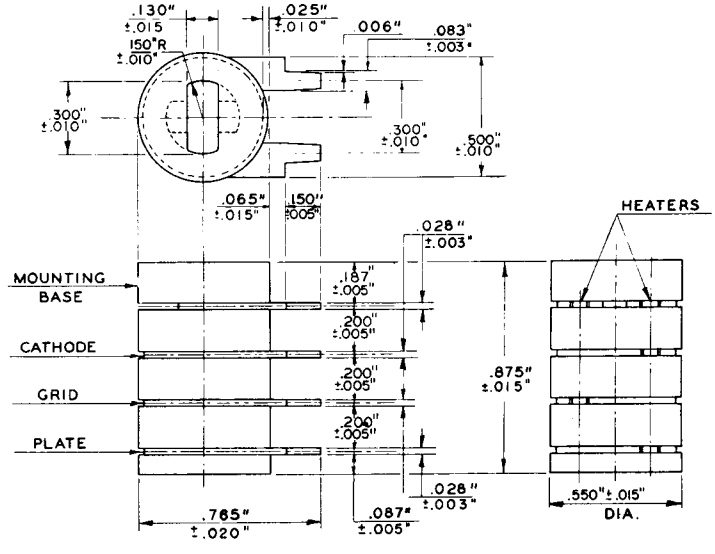
Intermittent Life Test

Statistical sample operated 1000 hours under the following conditions: Ef = 6.3 volts, Eb = 200 volts, Ecc = +6 volts, Ehk = −70 volts, Rk = 270 ohms, Rg = 0.1 meg. Heater voltage is cycled (on 1¾ hours, off ¼ hour). Tubes are evaluated, following 500 and 1000 hours of life test, for shorted or open elements, heater current, transconductance, negative grid current, noise figure, heater-cathode leakage, and interelectrode leakage resistance.



Interface Life Test

Statistical sample operated for 1000 hours with Ef = 6.6 volts, no other voltages applied, and evaluated for cathode interface resistance following the life test.



Heater-Cycling Life Test

Statistical sample operated for 2000 cycles minimum to evaluate and control heater-cathode defects. Conditions of test include Ef = 7.5 volts cycled for one minute on and one minute off, Eb = Ec = 0 volts, and Ehk = 70 volts with heater positive with respect to cathode. Following this test, tubes are evaluated for open heaters, heater-cathode shorts, and heater-cathode leakage current.

MAXIMUM RATINGS

ABSOLUTE-MAXIMUM VALUES

DC Plate Voltage	275	Volts
Peak Plate Voltage	400	Volts
Positive Peak and DC Grid Voltage	0	Volts
Negative Peak and DC Grid Voltage	50	Volts
Plate Dissipation	0.85	Watts
DC Cathode Current	3.8	Milliamperes
Heater-Cathode Voltage		
Heater Positive with Respect to Cathode	50	Volts
Heater Negative with Respect to Cathode	50	Volts
Grid Circuit Resistance, with Fixed Bias§	0.2	Megohms
Envelope Temperature at Hottest Point¶	250	C

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

CHARACTERISTICS AND TYPICAL OPERATION

AVERAGE CHARACTERISTICS

Plate Voltage	150	Volts
Cathode-Bias Resistor	1000	Ohms
Amplification Factor	80	
Plate Resistance, approximate	57000	Ohms
Transconductance	1400	Micromhos
Plate Current	0.95	Milliamperes
Grid Voltage, approximate Ib = 10 Microamperes, Eb = 250 Volts	−4.6	Volts

FOOTNOTES

* The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

† Heater current of a bogey tube at Ef = 6.3 volts.

‡ Without external shield.

§ If resistance is used in the cathode or plate circuits, the grid-circuit resistance may be high as (200,000 + 500 RK + 10 RL) ohms, where RK is the cathode-bias resistance in ohms, and RL is the DC plate load resistance in ohms.

¶ Operation below the rated maximum envelope temperature is recommended for applications requiring the longest possible tube life. The 7625 is also capable of operation at envelope temperatures much higher than the rated maximum values. For specific recommendations concerning higher temperature operation, contact your General Electric tube sales representative.

SPECIAL PERFORMANCE TESTS

	Maximum	
Variable-Frequency Vibration Ef = 6.3 volts, Ebb = 150 volts, Ec = 0 volts d-c, Rk = 1000 ohms (bypassed), R_L = 10000 ohms; Note 1	15	Millivolts peak to peak
Low-Frequency Vibration Ef = 6.3 volts, Ebb = 150 volts, Ec = 0 volts d-c, Rk = 1000 ohms (bypassed), R_L = 10000 ohms, G = 15, F = 40 cps; Note 2	0.75	Millivolts RMS

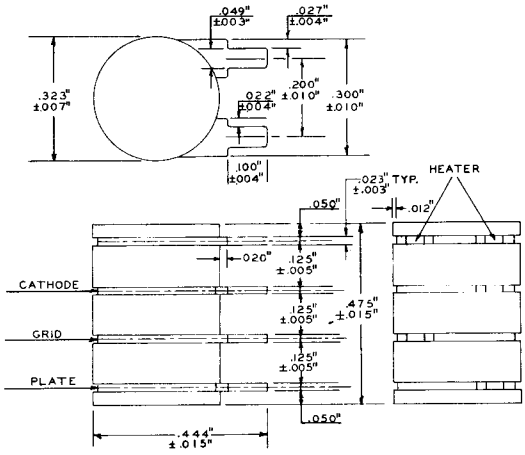
Low Pressure Voltage Breakdown Test
Statistical sample tested for voltage breakdown at a pressure of 8mm Hg, to simulate an altitude of 100,000 feet. Tubes shall not give visual evidence of flashover or corona when 300 volts RMS, 60 cps, is applied between the plate and grid terminals.

Note 1: The variable-frequency vibration test shall be performed as follows:
- a. The frequency shall be increased from 100 to 2000 cps with approximately logarithmic progression in 3 ± 1 minutes. The return sweep (2000 to 100 cps) is not required.
- b. The tube shall be vibrated with simple harmonic motion in each of two planes; first, parallel to the cylindrical axis; second, perpendicular to the cylindrical axis and parallel to a line through the major axis of a terminal lug.
- c. The peak acceleration shall be maintained at 10 ± 1 G throughout the test.
- d. The vibrational output produced across R_L as a result of the vibration shall be coupled to a low-pass filter that has the following characteristics:
  - (1) A response within ± 1 db of the response at 1000 cps over the frequency range of 100 to 17000 cps.
  - (2) The response shall be down at least 1.5 db at 20000 cps and have a cut-off rate of at least 18 db per octave above 20000 cps.

Note 2: The tube shall be vibrated with harmonic motion in each of two planes, (1) parallel to the cylindrical axis and (2) perpendicular to the cyclindrical axis and perpendicular to a line through the major axis of a terminal lug.

DEGRADATION RATE TESTS

Fatigue
Statistical sample vibrated for a total of six hours, three hours in each of two planes, at a peak acceleration of 10 G. Frequency is continuously varied from 30 cps to 2000 cps and back to 30 cps, with a period of ten minutes. Tubes are operated during the test with Ef = 6.3 volts, Eb = 150 volts, and Rk = 82 ohms. Following the test, tubes are evaluated for low frequency vibrational output, heater-cathode leakage, transconductance, and negative grid current.



Shock
Statistical sample subjected to 5 impact accelerations of approximately 450 G in each of four positions. The accelerating forces are applied by the Navy-type, High Impact (flyweight) Shock Machine using a 30° hammer angle. Tubes are operated during the test with Ef = 6.3 volts, Eb = 150 volts, Ehk = +100 volts, Rg = 0.1 Meg, and Rk = 82 ohms. Following the test, tubes are evaluated for low frequency vibrational output, heater-cathode leakage, transconductance, and negative grid current.

Stability Life Test
The statistical sample subjected to the Intermittent Life Test is evaluated for percent change in transconductance of individual tubes, from the initial readings to readings following 2 hours and 20 hours of the life test.

Survival Rate Life Test
The statistical sample subjected to the Intermittent Life Test is evaluated for shorted and open elements and transconductance following approximately 100 hours of life test.

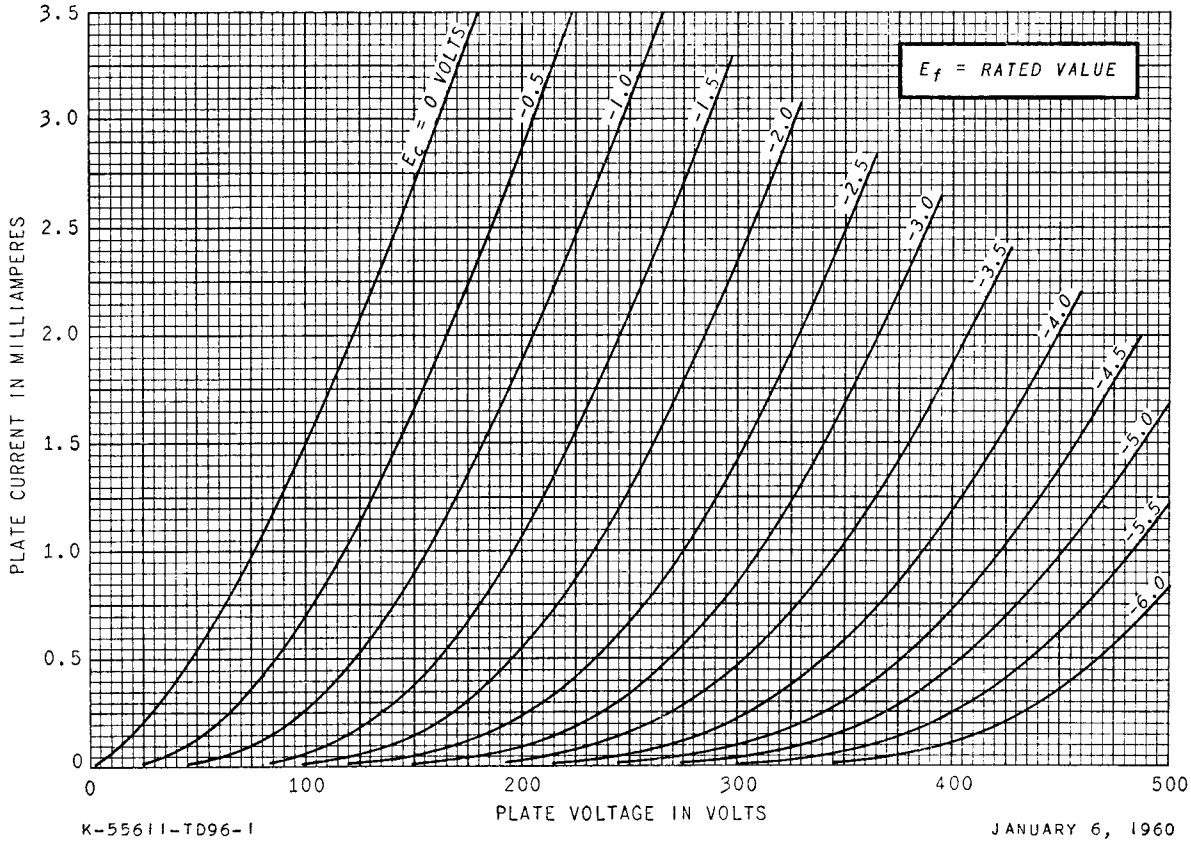
Intermittent Life Test
Statistical sample operated for 1000 hours under the following conditions: Ef = 6.3 volts (cycled—on 1¾ hours, off ¼ hour), Ebb = 300 volts, Ehk = +70 volts d-c, Rk = 82 ohms, R_L = 18000 ohms, and Rg = 0.1 meg. Tubes are evaluated, following 500 and 1000 hours of life test, for shorted or open elements, heater current, grid current, transconductance, heater-cathode leakage, and interelectrode leakage resistance.

DEGRADATION RATE TESTS (Continued)

Maximum eccentricity of insulators 0.010 in. from center line.

Interface Life Test

Statistical sample operated for 1000 hours with Ef = 6.6 volts, no other voltages applied, and evaluated for cathode interface resistance following the life test.



Heater-Cycling Life Test

Statistical sample operated for 2000 cycles minimum to evaluate and control heater-cathode defects. Conditions of test include Ef = 7.0 volts cycled for one minute on and one minute off, Eb = Ec = 0 volts, and Ehk = 70 volts with heater positive with respect to cathode. Following this test, tubes are evaluated for open heaters, heater-cathode shorts, and heater-cathode leakage current.

Note: The conditions for some of the indicated tests have deliberately been selected to aggravate tube failures for test and evaluation purposes. In no sense should these conditions be interpreted as suitable circuit operating conditions.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

PULSE-WELDER SERVICE—2000 AMPERES PEAK

ADAPTED TO WATER-FLOW CONTROL

The GL-7670 is a sealed, stainless-steel-jacketed, water-cooled ignitron designed to control the high-current, short-duration power pulses required in pulse-welding service. In such use two tubes in inverse-parallel connection will control 2000 amperes peak at voltages up to 2500 volts peak at a frequency of 60 cycles. The tube is also useful in other high-peak-current applications such as capacitor-discharge circuits.

The 7670 features a new coaxial construction in which current flows through the tube from anode to cathode, then up the tube wall to a coaxial cathode terminal at the top. This coaxial current flow provides a magnetic shield to eliminate the arc deflection which the high peak currents of this tube might cause in standard design ignitrons.

ADAPTED TO TEMPERATURE CONTROL

A slotted mounting plate permits convenient mounting of a thermostat to provide control of the water flow or over-temperature protection.

GL-7673

IGNITRON
Coaxial

RECTIFIER SERVICE—190 AMPERES
AC CONTROL SERVICE—355 AMPERES

ADAPTED TO WATER-FLOW CONTROL

The GL-7673 is a sealed, stainless-steel-jacketed, water-cooled ignitron for a-c control service. In such application two tubes in inverse-parallel connection will control 2400 kilovolt-amperes at voltages of 250 to 600 over a frequency range of 25 to 60 cycles.

The 7673 features a new coaxial construction in which current flows through the tube from anode to cathode, then up the tube wall to a coaxial cathode terminal at the top. This coaxial current flow provides a magnetic shield to eliminate the arc deflection which the high peak currents of this tube might cause in standard design ignitrons.

ADAPTED TO TEMPERATURE CONTROL

A slotted mounting plate permits convenient mounting of a thermostat to provide control of the water flow or over-temperature protection.

Advantages of the control feature include reduction of condensation on the tube walls during hot weather, protection against overloads, elimination of water supply as a limiting factor in equipment location, and appreciable savings in water consumption.

GL-7680

PACKAGED VOLTAGE-TUNABLE MAGNETRON

1000–2300 MEGACYCLES **1 WATT CW OUTPUT**

The GL-7680 is a packaged voltage-tunable magnetron for voltage-tunable operation in the 1000-to-2300-megacycle frequency range. It is a complete r-f power source package requiring only input power connections and an r-f power output connection and has a minimum CW power output of one watt across the entire frequency range. The tube may be voltage-tuned over a portion or all of the frequency range for which it is designed or operated at a fixed frequency. The voltage-frequency relationship is essentially linear.

GL-7681
IGNITRON

FREQUENCY-CHANGER WELDER SERVICE

The GL-7681 is a sealed, stainless-steel-jacketed, water-cooled, mercury-pool tube for use in electronic-contactor and resistance-welding-control service, both single-phase and three-phase.

In AC-control service two tubes in an inverse-parallel connection will control 1800 kilovoltamperes at 440 to 600 volts RMS, 25 to 60 cycles. Six tubes will control 2250 amperes peak at 1200 volts inverse in frequency-changer welder service.

AC-CONTROL SERVICE

A thermostat mounting plate, thermally coupled to the mercury-condensing surface of the tube, provides protection against excessive temperature or temperature control through regulation of the water flow.

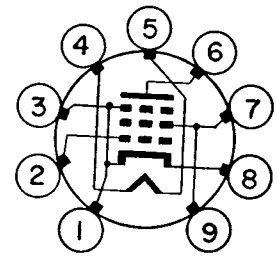
Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey tube of a specified type as defined by its published data, and should not be exceeded under the worst probable conditions.

These values are chosen by the tube manufacturer to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.



The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, variation in characteristics of all other tubes in the equipment, equipment control adjustment, load variation, signal variation, and environmental conditions.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

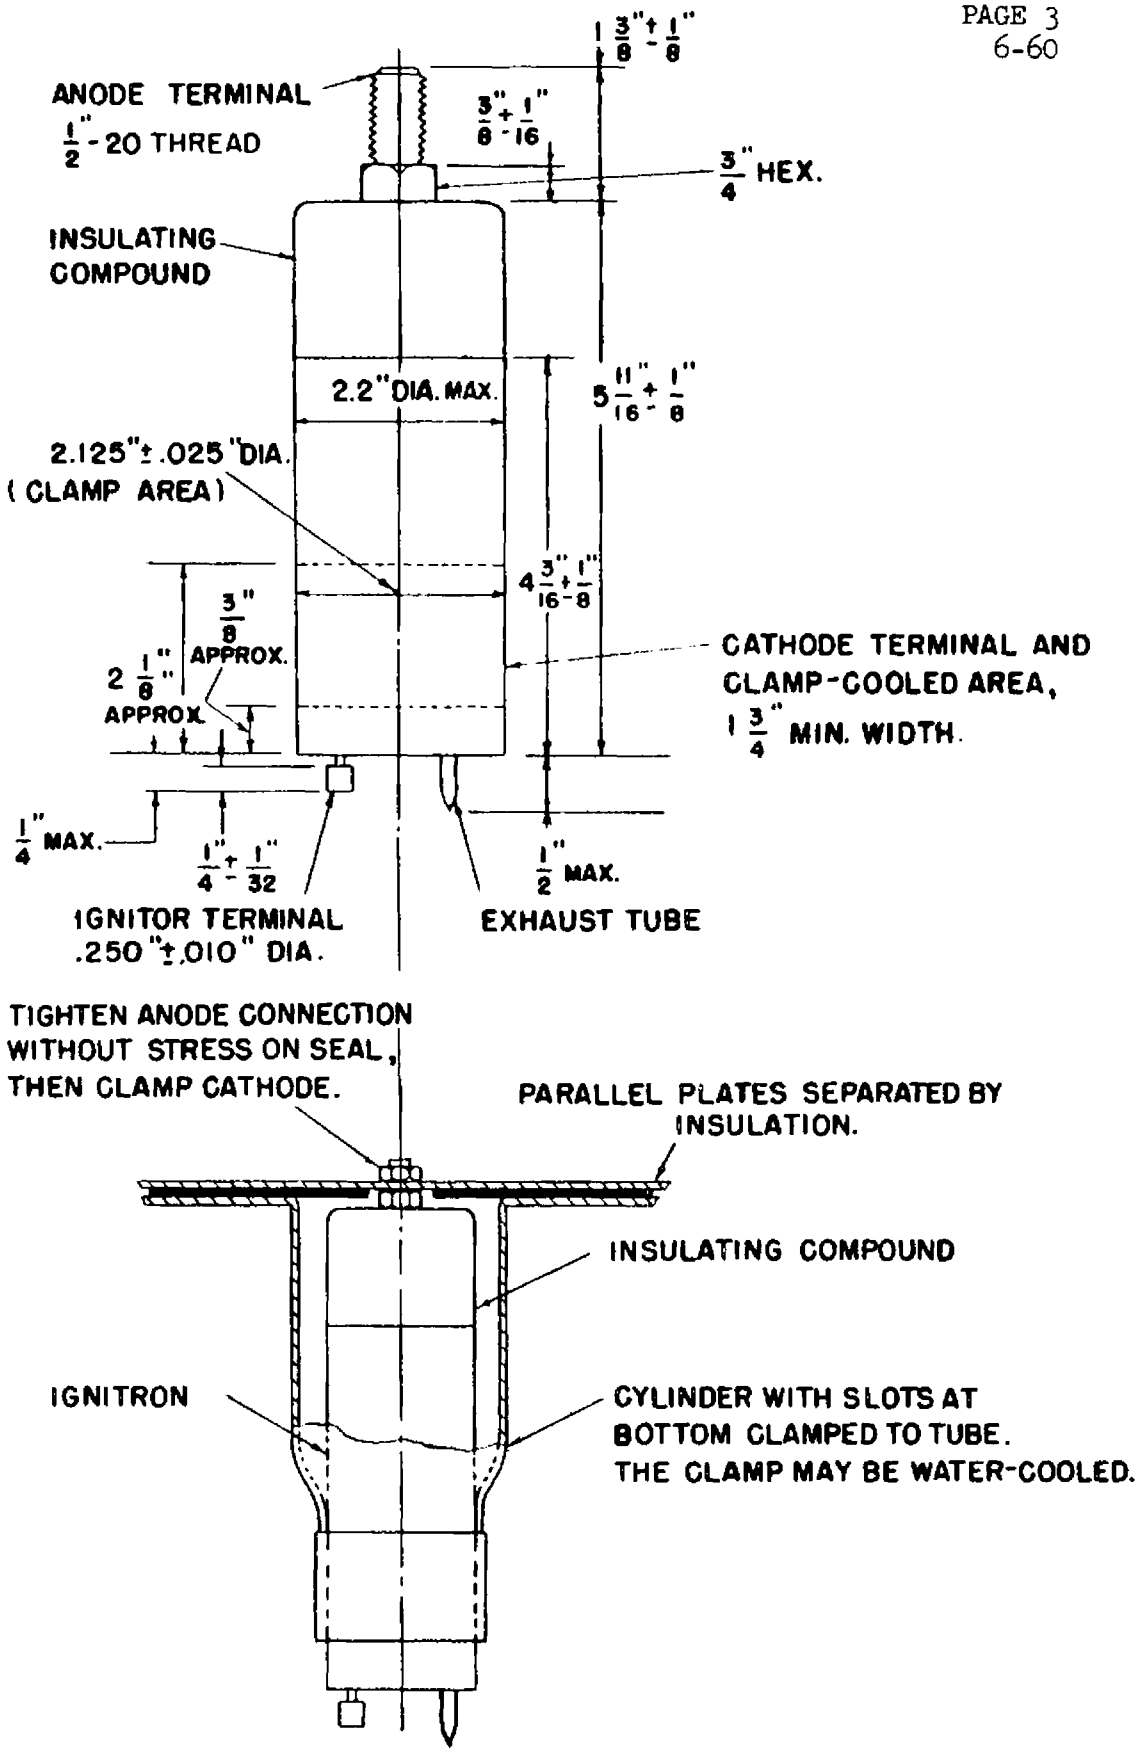
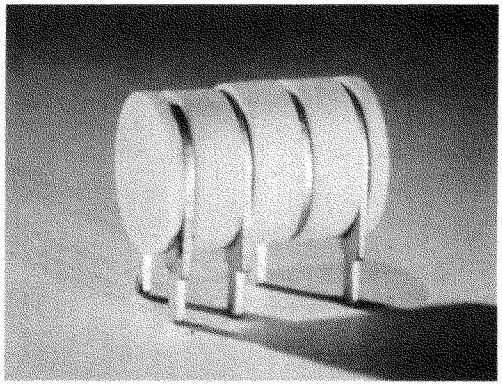
Anode Firing			
Ignitor Voltage			
Forward, maximum	—	3000	Volts
Inverse, maximum	—	5	Volts
Peak Ignitor Current	200	250	Amperes



*Anode-seal, insulating-compound temperature must always be higher than the cathode temperature to prevent mercury condensation on the anode and anode seal. Before tube operation, the anode seals must be heated long enough to vaporize all mercury from the seal area.

†The tube may become a closed switch (does not open) carrying current in both directions until the current dampens out.

‡The tube cannot hold off this voltage immediately after conduction. A 1-to-10-second delay may be required before reapplication of voltage.



¶Dampened oscillations are permissible provided the oscillating cycles do not exceed 20. The peak current value for one-half cycle must not be exceeded.

§Rate of rise depends on circuit.

CO-AXIAL TUBE MOUNT

METAL-CERAMIC TRIODE

DESCRIPTION AND RATING

The 7720 is a high-mu triode of ceramic-and-metal planar construction primarily intended for use as an oscillator in the ultra-high-frequency range.

* Dependent upon load conditions. For substantially constant load 0 C is satisfactory. For widely fluctuating loads 25 C is required.

+ At main anode voltages of 500 volts and over, the grid circuit should provide a negative d-c bias of 100 volts and a suitable turn-on voltage to swing the grid positive at the time the ignitor is fired. At lower anode voltages, it is sufficient to connect the grid to the main anode through a resistor. In either case, the grid circuit resistance should be 500 to 1000 ohms.

‡ RMS demand voltage, current, and kilovolt-ampere demand are all on the basis of full-cycle conduction (no phase delay) regardless of whether or not phase control is used. For voltages below the minimum, the minimum-voltage current rating applies. With the use of log-log paper straight-line interpolation between tabulated points may be used for other detailed ratings of: Demand kva vs average anode current, and maximum averaging time vs anode voltage.

SHEET-BEAM TUBE

Five-Star Tube

★ ★ ★ ★ ★

FOR INTERMEDIATE-FREQUENCY AMPLIFIER AND LIMITER APPLICATIONS

The 7763 is a miniature double-plate sheet-beam tube which incorporates a pair of balanced deflectors to direct the electron beam to either of the two plates. It is especially suited for service as an intermediate-frequency amplifier and limiter in systems that require constant phase-shift over a wide range of input signal amplitudes.

The 7763 is a special-quality tube intended for use in critical industrial and military applications in which operational dependability is of primary importance. Features of the tube include a high degree of mechanical strength and a heater-cathode construction capable of withstanding many-thousand cycles of intermittent operation.

Heater Positive with Respect to Cathode	100	Volts
Heater Negative with Respect to Cathode	100	Volts
Deflector Circuit Resistance	39000	Ohms

Absolute-maximum ratings are limiting values of operating and environmental conditions applicable to any tube of a specified type as defined by its published data, which should not be exceeded under the worst probable conditions. The tube manufacturer chooses these values to provide acceptable serviceability of the tube, taking no responsibility for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other tubes in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variations, signal variation, environmental conditions, and variations in characteristics of the tube under consideration and of all other tubes in the equipment.

METAL-CERAMIC TRIODE

DESCRIPTION AND RATING

FOR BROADBAND RADIO-FREQUENCY AMPLIFIER APPLICATIONS

The 7768 is a high-mu triode of ceramic-and-metal planar construction primarily intended for use as a broadband radio-frequency amplifier. The 7768 is especially suited for use where unfavorable conditions of mechanical shock, mechanical vibration, and nuclear radiation are encountered.

SPECIAL PERFORMANCE TESTS

	Min.	Bogey	Max.	
Grid Recovery				
Change in Average Plate Current	.....	.....	1.0	Milliamperes
Peak Plate Current Backswing	.....	.....	2.0	Milliamperes

Tubes with poor grid recovery affect circuit operation when the grid is driven positive by a pulse of signal or noise, somewhat as if a parallel RC circuit were in series with the grid. This effect may occur in tubes of any type, but is unimportant in many applications. In the majority of 7768 tubes the effect is negligible, but to eliminate the few in which it may be excessive, tubes are tested under the following conditions: Ef = 6.3 volts, Ebb = 250 volts, R_L = 0.01 meg. Ec is adjusted for Ib = 10 ma.

Upon application to the grid of a 3 volt positive pulse (prr = 60 pps, duty factor = 0.0012) the change in average plate current is noted, and the peak plate current backswing is measured. The following diagram shows qualitatively the plate current-time relationship for a tube (with poor grid recovery) subjected to this test.

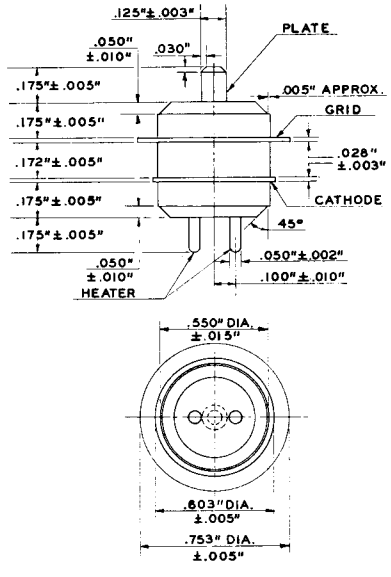
Low Frequency Vibrational Output	.....	.....	50	Millivolts RMS

Statistical sample is subjected to vibration in each of two planes at 40 cps, with peak acceleration 15G. Tube is operated with Ef = 6.3 volts, Ebb = 250 volts, Rk = 68 ohms (bypassed), R_L = 2000 ohms

Low Pressure Voltage Breakdown Test

Statistical sample tested for voltage breakdown at a pressure of 8mm Hg, to simulate an altitude of 100,000 feet. Tubes shall not give visual evidence of flashover or corona when 300 volts RMS, 60 cps, is applied between the plate and grid terminals.

OUTLINE DRAWING



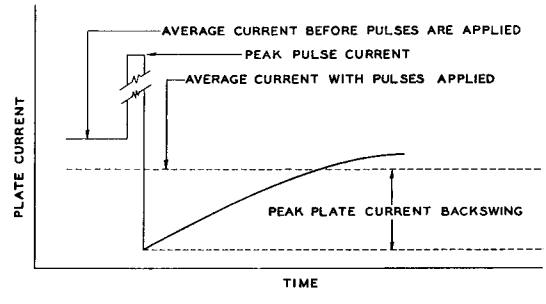


PLATE CURRENT VS. TIME —GRID RECOVERY TEST

DEGRADATION RATE TESTS

Fatigue

Statistical sample vibrated for a total of six hours, three hours in each of two planes, at a peak acceleration of 10G. Frequency is continuously varied from 30 cps to 2000 cps and back to 30 cps, with a period of ten minutes. Tubes are operated during the test with Ef = 6.3 volts, Eb = 250 volts, and Rk = 68 ohms. Following the test, tubes are evaluated for low frequency vibrational output, heater-cathode leakage, heater current, and transconductance.

Shock

Statistical sample subjected to 5 impact accelerations of approximately 450G in each of four positions. The accelerating forces are applied by the Navy-type, High Impact (flyweight) Shock Machine using a 30° hammer angle. Tubes are operated during the test with Ef = 6.3 volts, Eb = 250 volts, Ehk = +100 volts, and Rk = 68 ohms. Following the test, tubes are evaluated for low frequency vibrational output, heater-cathode leakage, heater current, and transconductance.

Stability Life Test

The statistical sample subjected to the Intermittent Life Test is evaluated for percent change in zero-bias transconductance of individual tubes, from the initial reading to readings following 2 hours and 20 hours of the life test.

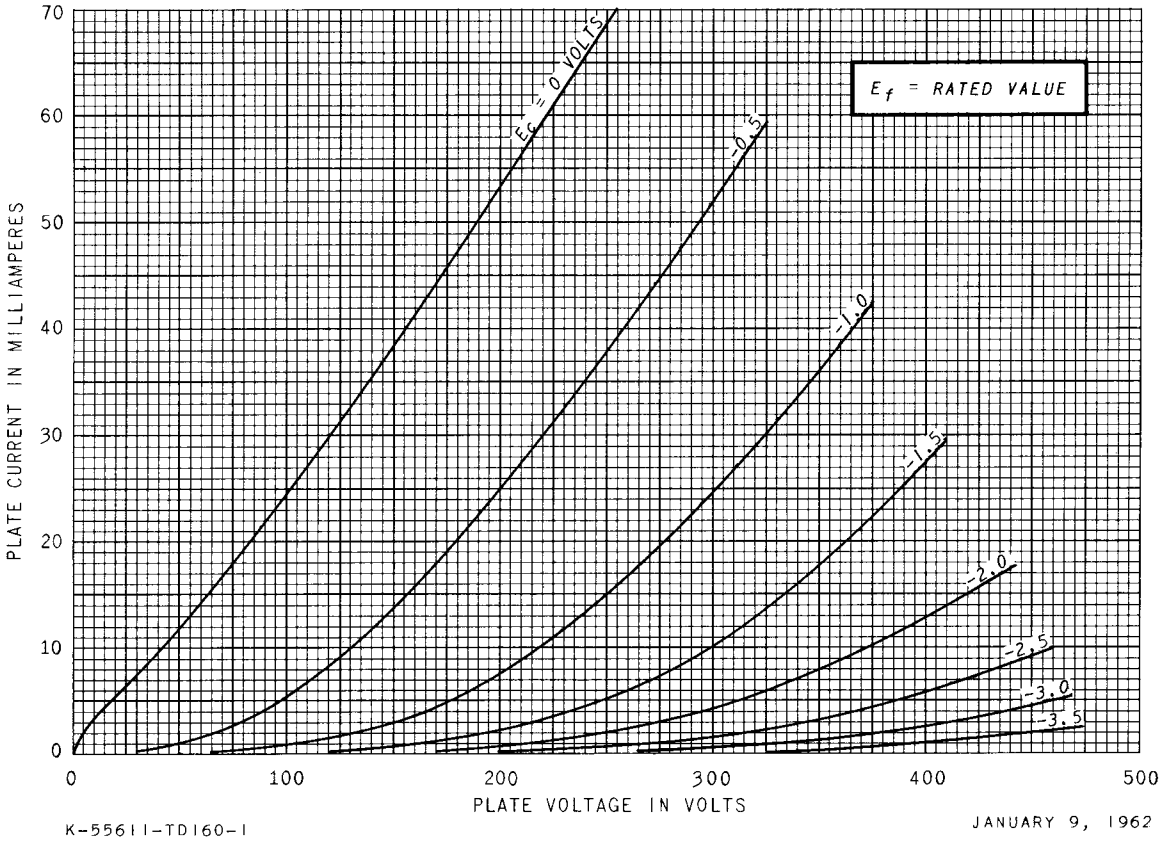
Survival Rate Life Test

The statistical sample subjected to the Intermittent Life Test is evaluated for shorted and open elements and transconductance following approximately 100 hours of life test.

Intermittent Life Test

Statistical sample operated for 1000 hours under the following conditions: Ef = 6.3 volts (cycled—on 1¾ hours, off ¼ hour), Eb = 200 volts, Ecc = +7 volts, Ehk = −70 volts d-c, Rk = 270 ohms, and Rg = 0.01 meg. Tubes are evaluated, following 500 and 1000 hours of life test, for shorted or open elements, heater current, grid current, transconductance, noise figure, heater-cathode leakage, and interelectrode leakage resistance.

Interface Life Test



Statistical sample operated for 1000 hours with Ef = 6.6 volts, no other voltages applied, and evaluated for cathode interface resistance following the life test.

Heater-Cycling Life Test

Statistical sample operated for 2000 cycles minimum to evaluate and control heater-cathode defects. Conditions of test include Ef = 7.5 volts cycled for one minute on and one minute off, Eb = Ec = 0 volts, and Ehk = 70 volts with heater positive with respect to cathode. Following this test, tubes are evaluated for open heaters, heater-cathode shorts, and heater-cathode leakage current.

Note: The conditions for some of the indicated tests have deliberately been selected to aggravate tube failures for test and evaluation purposes. In no sense should these conditions be interpreted as suitable circuit operating conditions.

Planar Triode

7784

FOR GROUNDED-GRID CLASS A UHF AMPLIFIER APPLICATIONS

The 7784 is a high-mu, metal-and-ceramic triode intended for operation as a grounded-grid, Class A radio-frequency amplifier at frequencies as high as 3000 megacycles.

Features of the tube include small size, planar electrode construction with close spacing, inherent rigidity, and an envelope structure convenient for coaxial circuit applications.

At 1200 megacycles a noise figure of less than 8.5 decibels may be obtained when the 7784 is used in a grounded-grid coaxial circuit.

The 7784 differs from the 6299 only in having an isolated heater.

NOTES

* The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

‡ Heater current of a bogey tube at Ef = 6.3 volts.

§ Without external shield.

¶ The electrical connections to the plate and cathode must provide good thermal conductivity from these electrodes. The plate contact must be sufficiently flexible to keep the lateral force on the plate terminal at a minimum.

The 7784 is rated only for Class A amplifier service.

Δ Does not apply to initial-emission-velocity current

¢ Adjusted for Ib = 10 milliamperes.

** Adjust for Ib = 10 milliamperes; range must be variable from 75 to 200 volts.

‡‡ Supply should be regulated.

§§ For operation above 1000 megacycles, the minimum noise figure will generally be obtained by operation at zero bias. For operation below 1000 megacycles, the use of a cathode resistor or grid bias should be evaluated for the particular application.

¶¶ Adjusted for Ib = 10 milliamperes; 200-ohm variable cathode resistor recommended.

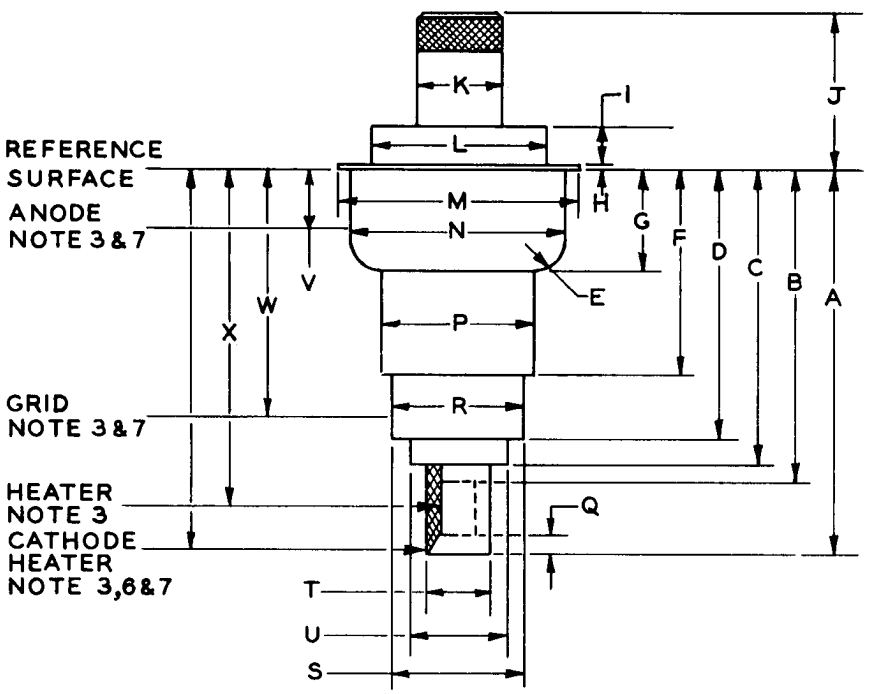
Peak Useful Power Output, approximate	1500	Watts

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron device of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The device manufacturer chooses these values to provide acceptable serviceability of the device, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the device under consideration and of all other electron devices in the equipment.



The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any device under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the device under consideration and of all other electron devices in the equipment.

NOTES

* The equipment designer should design the equipment so that heater voltage is centered at some value within the range of 5.0 to 6.0 volts. Heater voltage variations about the center value should be kept as small as practical and should not, in any case, exceed ±5%. The optimum center value of heater voltage depends on the cathode current and on other parameters of circuit design and operation. For specific recommendations, contact your General Electric tube sales representative.

‡ Heater Current of a bogey tube at Ef = 6.0 volts.

§ Measured without heater voltage.

TRIGGERED SPARK GAP

MINIATURE SWITCHING DEVICE **3 KILOVOLTS**

18 JOULES

The GL-7964 is a small, cold cathode, gaseous, triggered spark gap capable of switching 18 joules of energy at high voltages. Since the device does not require external energy to initiate the discharge its use permits both equipment cost reduction and savings in space through component elimination.

Mechanical features include rugged metal-ceramic construction, ability to withstand high shock and vibration conditions, and reliable operation over temperatures ranging from as low as −80 to as high as +200 F.

The GL-7964 is especially designed to deliver short rapid pulses of current with minimum delay and jitter in applications where high hold-off voltages and low leakage currents exist.

Applications include switching single stored electrical energy systems into low impedance loads, or energy storage capacitors into resistive or inductive loads.

7984

COMPACTRON BEAM PENTODE

FOR RADIO-FREQUENCY POWER AMPLIFIER APPLICATIONS

DESCRIPTION AND RATING

The 7984 is a compactron beam pentode designed for use as a radio-frequency power amplifier in mobile communications equipment. In this service, it is capable of delivering a power output of 46 watts* at 175 megacycles.

Features of the 7984 include a single-ended construction, low seated height, short internal leads, multiple cathode and screen connections, and low driving-power requirements.

MAXIMUM RATINGS

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

NOTES

* This is the power output of the tube. Power output measured at the load will be less because of tank-circuit losses.

‡ The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

§ Heater current of a bogey tube at Ef = 13.5 volts.

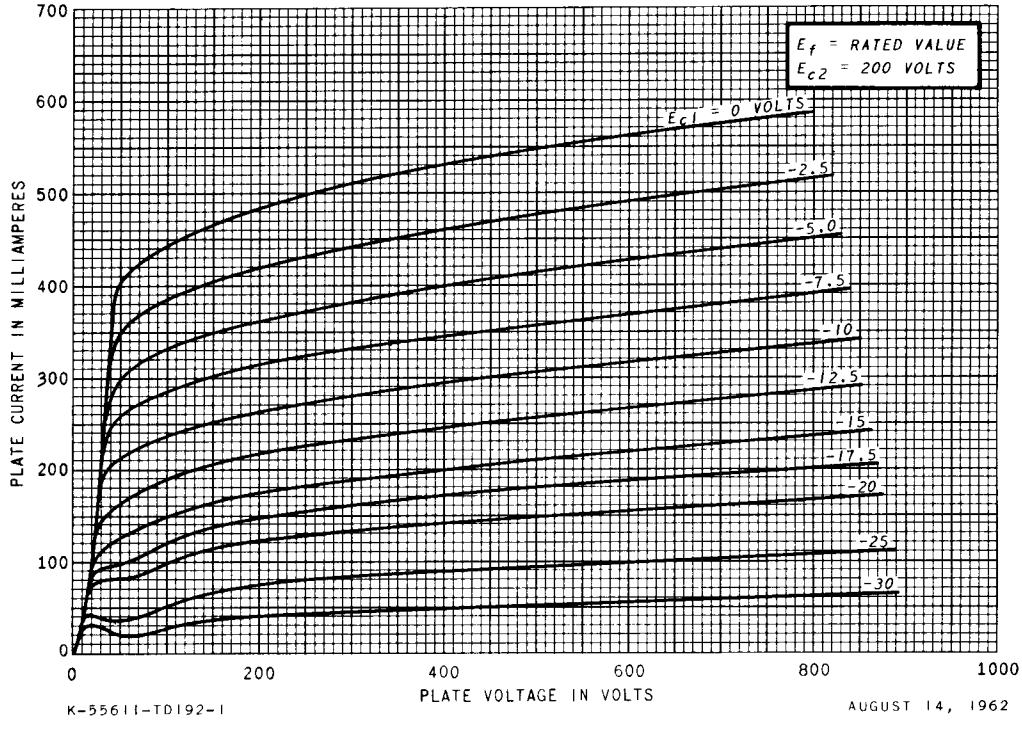
¶ Without external shield.

\# Continuous Commercial Service (CCS) is defined as that type of service in which normal tube life and reliability of performance under continuous operating conditions are the prime consideration.

△ Intermittent Commercial and Amateur Service (ICAS) is defined to include the many applications where the transmitter design factors of minimum size, light weight, and considerably increased power output are more important than long tube life. In this service, life expectancy may be one-half that obtained in Continuous Commercial Service.

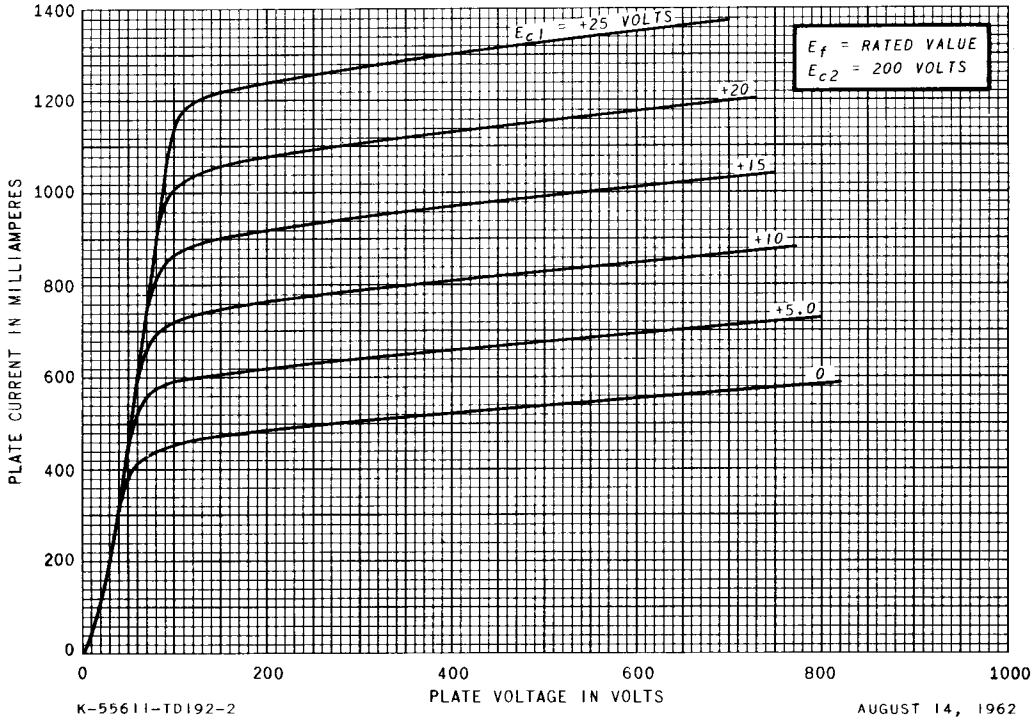
Under the ICAS classification are such applications as the use of tubes in amateur transmitters, and the use of tubes in equipment where transmissions are of intermittent nature. The term "intermittent" is used to identify operation conditions in all applications other than amateur in which no operating or "on" period exceeds 5 minutes and every "on" period is followed by an "off" or standby period of at least the same or greater duration.

NOTES (Cont'd)



** Intermittent Mobile Service (IMS) is defined to include those applications, such as aircraft, where the transmitter design factors of minimum size, light weight, and exceedingly high power output for short intervals are the primary requirements, even though the average life expectancy of tubes used in such transmitters is reduced. Tube ratings for IMS service are established on the basis that the transmissions have maximum "on" periods of 15 seconds followed by "off" periods of at least 60 seconds, except that it is permissible to make equipment tests with maximum "on" periods of 5 minutes followed by "off" periods of at least 5 minutes provided the total "on" time of such periods does not exceed 10 hours during the life of any tube.

Although the use of tubes under IMS ratings involve great reduction in tube life, such use can be justified as economical practice in applications where high power is intermittently desired for small tubes.



‡‡ Socket contacts for these three pins should be connected together.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

GL-7998
COAXIAL IGNITRON

FREQUENCY-CHANGER WELDER SERVICE
2250 AMPERES PEAK

The GL-7998 is a sealed, stainless-steel-jacketed, water-cooled ignitron for use in electronic-contactor and resistance-welding-control service, both single-phase and three-phase. It is a coaxial-design version of the GL-7681.

In AC-control service two tubes in an inverse-parallel connection will control 1800 kilovolt-amperes at 440 to 600 volts RMS, 25 to 60 cycles. In frequency-changer welder service six tubes will control 2250 amperes peak at 1200 volts inverse.

In the coaxial construction current flows through the tube from anode to cathode, then up the tube wall to a coaxial cathode terminal at the top. This current flow provides a magnetic shield which eliminates the arc deflection that the high peak currents possible with this tube might cause in standard design ignitrons.

AC-CONTROL SERVICE
1800 KILOVOLT-AMPERES

A thermostat mounting plate thermally coupled to the mercury-condensing surface of the tube facilitates attachment of a thermostat to provide either protection against excessive temperature or temperature control through regulation of the water flow.

MAXIMUM RATINGS

Absolute-Maximum Values

Plate Voltage	250	Volts
Peak Plate Voltage	400	Volts
Positive Peak and DC Grid-to-Cathode Voltage	0	Volts
Negative Peak and DC Grid-to-Cathode Voltage	50	Volts
Plate Dissipation	1.1	Watts
DC Cathode Current	11	Milliamperes
Heater-Cathode Voltage		
Heater Positive with Respect to Cathode	50	Volts
Heater Negative with Respect to Cathode	50	Volts
Grid-Circuit Resistance, with Fixed BiasΔ	0.01	Megohms
Envelope Temperature at Hottest Point#	250	C

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

CHARACTERISTICS AND TYPICAL OPERATION

Average Characteristics

Plate Voltage	150	Volts
Grid Voltage	+6.0	Volts
Cathode-Bias Resistor	910	Ohms
Amplification Factor	94	
Plate Resistance, approximate	9000	Ohms
Transconductance	10500	Micromhos
Plate Current	7.2	Milliamperes
Grid Voltage, approximate		
Ib = 100 Microamperes	-2.2	Volts

+ The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

‡ Heater current of a bogey tube at Ef = 6.3 volts.

§ Without external shield.

¶ One method of mounting the 8083 is to use a stainless-steel "T" bolt (see drawing) to attach the mounting base of the tube to a chassis or circuit board. The "T" bolt should be inserted in the slot in the base of the tube, turned 90 degrees, and attached to the chassis or circuit board with a 2-56 nut and lock washer. Torque used to tighten the nut should not exceed 3 inch-pounds.

Δ If resistance is used in the cathode or plate circuits, the grid-circuit resistance may be as high as (10000 + 100 RK + 10RL) ohms, where RK is the cathode-bias resistance in ohms, and RL is the DC plate load resistance in ohms.

Operation below the rated maximum envelope temperature is recommended for applications requiring the longest possible tube life.

8/18/61 (E)

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

GL-8092

IMAGE ORTHICON

EXCEPTIONAL SENSITIVITY 3 IN. DIAMETER, MAXIMUM LONG LIFE

MAGNETIC FOCUS AND DEFLECTION COLOR AND BLACK-AND-WHITE FIELD MESH

The GL-8092 is a television camera tube primarily intended for live color-pickup service where normal lighting conditions are not available. This includes the range of applications from most remotes to black-and-white illuminated studios.

The tube features a high-gain, thin-film semiconductor target, which results in extremely high sensitivity and ability to handle wide ranges of scene illumination. The tube will produce color pictures of good quality at a scene illumination of approximately 40 foot-candles, and black-and-white pictures at light levels of approximately 1 foot-candle.

Particularly important for color service is the addition of a field mesh in the scanning section which provides an excellent landing, shading, and dynamic match in color cameras utilizing three image orthicons for the simultaneous method of pickup.

Other significant advantages of the thin-film semiconductor target include excellent resolution and high amplitude response, elimination of stickiness throughout life, greatly reduced susceptibility to permanent burn-in damage, stable operation during life and elimination of target raster burns.

A photocathode with a spectral response close to that of the eye provides accurate color rendition of scenes by assuring gray-scale reproduction of colors in nearly their true tonal gradation.

The GL-8092 is interchangeable with the GL-7629, -7293, -5820 and 7513.

GL-8093

IMAGE ORTHICON

FIELD MESH **3 IN. DIAMETER, MAXIMUM**

MAGNETIC FOCUS AND DEFLECTION

The GL-8093 is a television camera tube for studio pickup service where high quality of performance is required and lighting can be controlled.

The construction of the target-mesh assembly assures a high signal-to-noise ratio, particularly desirable for video-taping requirements. The GL-8093 also features a field mesh in the scanning section which enhances picture quality by providing sharp transition from black to white without spurious effect (white edges) and by improving flatness of field and corner resolution.

A suppressor grid maintains high signal-to-noise ratio by preventing field-mesh secondary electrons from entering the electron multiplier.

A photocathode with a spectral response close to that of the eye permits portrayal of scenes in nearly their true tonal gradation.

In operation alignment is performed with the lens open on a chart or scene since dynode aperatures are not visible with the lens capped.

The tube is interchangeable with the GL-5820, -7293 and 7513.

GL-8138

TRIGGERED SPARK GAP

MINIATURE SWITCHING DEVICE **3 KILOVOLTS**

18 JOULES

The GL-8138 is a small, cold cathode, gaseous, triggered spark gap capable of switching 18 joules at high voltages. Since the device does not require such external sources of energy as "keep-alive" circuits to initiate the discharge, its use permits both equipment cost reduction and savings in space through component elimination.

Mechanical features include rugged metal-ceramic construction, gold-plated terminals to resist corrosion, ability to withstand high shock and vibration conditions, and reliable operation over temperatures ranging from as low as −80 to as high as +300 F.

The GL-8138 is especially designed to deliver short rapid pulses of current with minimum delay and jitter in applications where high hold-off voltages and low leakage currents exist.

Applications include switching single-stored electrical-energy systems into low-impedance loads, or energy-storage capacitors into resistive or inductive loads.

25 DB GAIN **METAL-CERAMIC**
LOW NOISE

The GL-8154 is a ruggedized, low-noise, broadband traveling-wave tube for use in the 7000-to-11,000 megacycle frequency range. It has a noise figure of less than 10 decibels across the entire band with a power output of 5 milliwatts.

The tube is of metal-and-ceramic construction and is supplied as a complete packaged assembly which includes permanent focusing magnets, connectors, and housing. The entire assembly weighs approximately 11.5 pounds.

The broad bandwidth, low-noise, high gain, freedom from tuning adjustments, and rugged construction make this tube particularly useful in military systems. As the input tube for radar receivers, it has the decided advantages of low noise and protection to the crystal mixer. Other applications include electronic countermeasures equipment, microwave relay systems, and radiometry.

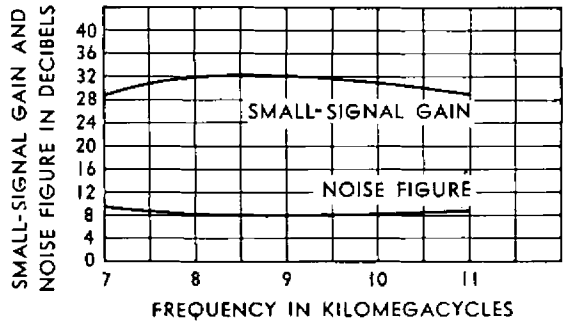
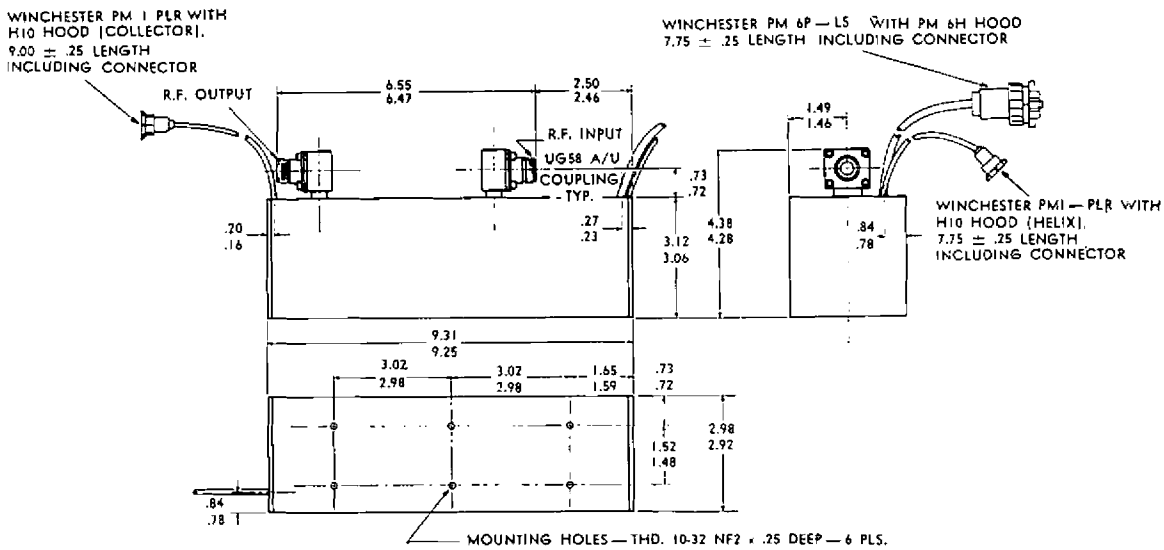
Collector Voltage	900 to 1000	Volts
Beam Current	400 to 700	Microamperes
Magnetic Field Strength, approximate	600	Gausses

* Over band with the same operating voltages that provide minimum gain variation.
† An improved noise figure is possible when this tube is optimized for a narrow frequency band. If requirements exist for an improved noise figure over a narrow band, consult the nearest Power Tube Department sales office.
**All voltages may be isolated from ground; i.e., it is not necessary to operate the cathode, helix, collector, or any other electrode at ground potential. Voltages shown are measured with respect to cathode. For minimum noise and optimum gain characteristics, voltages should be adjusted within ranges specified by instructions accompanying each tube.

GENERAL ELECTRIC



PERMANENT-MAGNET PRECAUTIONS



This tube uses a uniform-field permanent magnet as the focusing structure. A label on the tube specifies a nominal lower limit of two inches on magnetic-material proximity. It must be realized that strong external magnets or large amounts of magnetic material at this distance may permanently damage the tube. A small screwdriver will not, while a large a-c transformer or a large sheet of steel at this distance may cause damage by defocusing the tube.

In addition, a related caution is important and must be remembered whenever handling a uniform-field tube. The permanent magnets of these tubes cause a large attractive force between the tube and magnetic material. Unless one is always careful to hold the tube and/or magnetic objects near the tube firmly, the result is sudden direct contact. The magnetic object may cause tube damage due to violations of the minimum spacing requirement.

For small steel hand tools, a two-inch limit is sufficient. For large magnetic objects with magnetic fields of their own, the lower minimum distance should be determined accurately by testing. To accomplish this, the tube may be secured to a suitable three-foot-long dielectric support and the tube case grounded. With the tube operating and its helix current being measured, the tube may be moved slowly by the dielectric support toward the magnetic object. (CAUTION: Appropriate electrical safety procedures should be followed at all times.) The minimum distance for which there is no degradation in r-f performance is the point at which the helix current starts to increase. If a slight degradation in noise figure can be accepted, the helix current may be allowed to increase somewhat as long as it stays below its operating maximum.

MAXIMUM RATINGS

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

NOTES

* The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

‡ Heater current of a bogey tube at Ef = 13.5 volts.

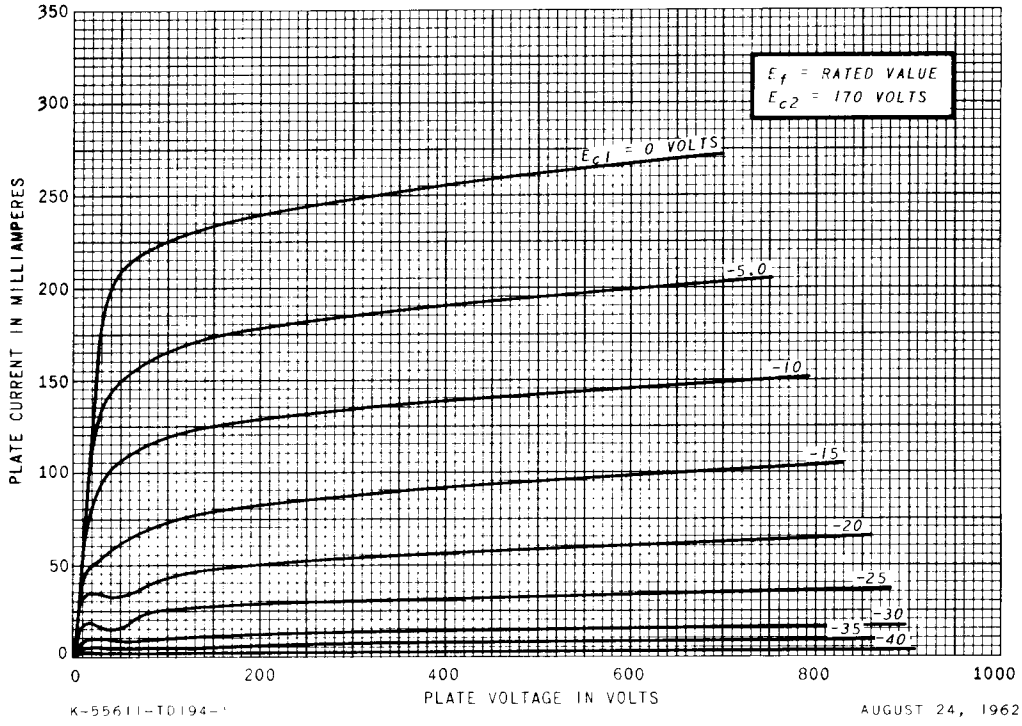
§ Without external shield

¶ Continuous Commercial Service (CCS) is defined as that type of service in which normal tube life and reliability of performance under continuous operating conditions are the prime consideration.

\# Intermittent Commercial and Amateur Service (ICAS) is defined to include the many applications where the transmitter design factors of minimum size, light weight, and considerably increased power output are more important than long tube life. In this service, life expectancy may be one-half that obtained in Continuous Commercial Service.

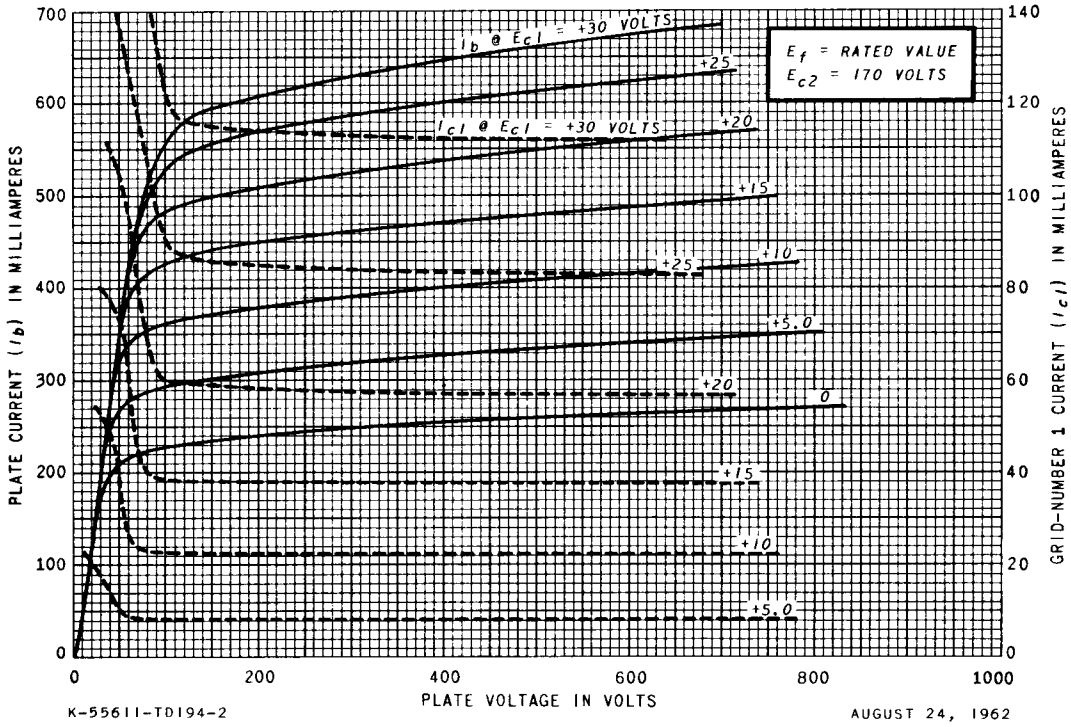
Under the ICAS classification are such applications as the use of tubes in amateur transmitters, and the use of tubes in equipment where transmissions are of an intermittent nature. The term "intermittent" is used to identify operation conditions in all applications other than amateur in which no operating or "on" period exceeds 5 minutes and every "on" period is followed by an "off" or standby period of at least the same or greater duration.

NOTES (Cont'd)



Δ Intermittent Mobile Service (IMS) is defined to include those applications, such as aircraft, where the transmitter design factors of minimum size, light weight, and exceedingly high power output for short intervals are the primary requirements even though the average life expectancy of tubes used in such transmitters is reduced. Tube ratings for IMS service are established on the basis that the transmissions have maximum "on" periods of 15 seconds followed by "off" periods of at least 60 seconds, except that it is permissible to make equipment tests with maximum "on" periods of 5 minutes followed by "off" periods of at least 5 minutes provided the total "on" time of such periods does not exceed 10 hours during the life of any tube.

Although the use of tubes under IMS ratings involve great reduction in tube life, such use can be justified as economical practice in applications where high power is intermittently desired from small tubes.



** Socket contacts for these three pins should be connected together.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

GL-8205
COAXIAL IGNITRON

AC-CONTROL SERVICE

4800 KILOVOLT-AMPERES

HIGH EFFICIENCY COOLING

The GL-8205 is a sealed, stainless-steel-jacketed ignitron for a-c control welder service. It is a coaxial-design version of the GL-7151.

Two tubes in an inverse-parallel connection will control 4800 kilovolt-amperes at 250 to 600 volts RMS, 25 to 60 cycles.

In the coaxial construction, current flows through the tube from anode to cathode, then up the tube wall to a coaxial cathode terminal at the top. This current flow provides a magnetic shield which eliminates the arc deflection that the high peak currents possible with this tube might cause in standard-design ignitrons.

Other features of the 8205 include a specially designed water-cooling chamber that provides high-efficiency cooling at the bottom of the tube without increasing the water-pressure drop of the cooling jacket. A thermostat mounting plate, thermally coupled to the mercury-condensing surface of the tube, facilitates attachment of a thermostat to provide either protection against excessive temperature or temperature control through regulation of the water flow.

* The time interval between the point on the rising portion of the grid pulse which is 26 percent of the peak unloaded pulse amplitude and the start of the anode current pulse.

† Change in anode delay time relative to the delay time observed after two minutes of operation.

‡ Driver pulse measured at the tube socket with thyratron grid disconnected; amplitude = 1300 volts minimum, 2500 volts maximum, above 0; time of rise = 0.35 microsecond maximum, measured from 26 percent to 70 percent of peak value; grid pulse duration = 2 microseconds minimum, measured between 70 percent of peak on rising side to 70 percent of peak on falling side; impedance of drive circuit = 10 to 25 ohms.

¶ The RMS current of hydrogen thyratrons is the square root of the product of the average and peak currents.

§ Highest rating to which tube has been tested. This is not necessarily maximum tube capability.

GENERAL ELECTRIC

from JEDEC release #3970, Nov. 12, 1962

OPERATING NOTES

Thermal

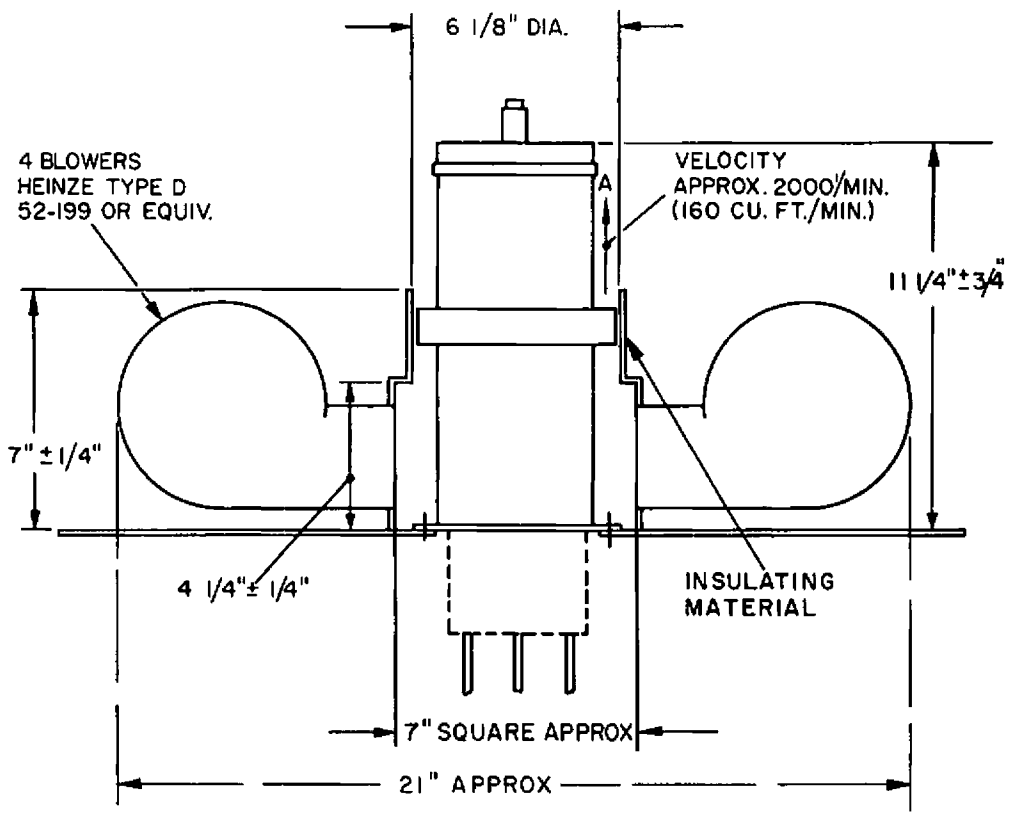
The optimum reservoir voltage for operation under artificial-cooling conditions at maximum tube voltage, maximum peak and average tube currents, and at a repetition corresponding to an anode dissipation factor of 50 x 10^9 is inscribed on the base of the tube and must be held within ±5 percent. Applications involving operation at other conditions may necessitate a redetermination of the optimum reservoir range.

Electrical

In switching and line-type modulator circuits the minimum inverse anode voltage permissible is 5 percent of the peak forward voltage, and the maximum is 5000 volts during the first 25 microseconds following the anode pulse, exclusive of a spike of 0.05 microsecond maximum duration.

If the forward anode voltage is applied instantaneously, it should be limited to a maximum of 22 kilovolts peak. The power-supply filter should be designed to limit the rate of application of this voltage to 550,000 volts per second.

X-RAY WARNING NOTICE



If the GL-8326 is operated at anode voltages in excess of 16 kilovolts, X-ray radiation shielding may be necessary to protect the user against possible danger of personal injury from prolonged exposure at close range. GENERAL ELECTRIC

GL-8420

COAXIAL IGNITRON

INTEGRAL CONTROL THERMOSTAT FORCED-AIR COOLED

ELECTRONIC CONTACTOR SERVICE 1000 AMPERES

The GL-8420 is a forced-air-cooled ignitron for use in railroad locomotive service as an electronic contactor. In such application two tubes in an inverse-parallel connection control the a-c voltage input to a semiconductor rectifier.

Features include a coaxial construction in which current flows from anode to cathode, then up the tube wall to a coaxial cathode terminal. Coaxial current flow provides a magnetic shield to eliminate arc deflection caused by high peak currents. An integral thermostat provides protection against excessive temperature and loss of cooling air. An ignitor terminal block on the periphery of the tube facilitates connecting to the ignitor.

Total DC and Peak	200	200	Volts

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of all other electron devices in the equipment.

SPECIAL PERFORMANCE TESTS

	Min.	Max.	
Oscillator Power Output			
Tubes are tested for power output as an oscillator under the following conditions: Ef = 5.0 volts; F = 2500 MC, min; Eb = 1000 volts; Ib = 90 ma	15	---	Watts
Low Pressure Voltage Breakdown Test			
Statistical sample tested for voltage breakdown at a pressure of 27 mm Hg. Tubes shall not give visual evidence of flashover when 1000 volts RMS, 60 cps, is applied between the plate and grid terminals			

* The equipment designer should design the equipment so that heater voltage is centered at some value within the range of 4.5 to 6.3 volts. Heater voltage variations about the center value should be kept as small as practical and should not, in any case, exceed ±5%. The optimum center value of heater voltage depends on the cathode current and on other parameters of circuit design and operation. For specific recommendations, contact your General Electric tube sales representative.

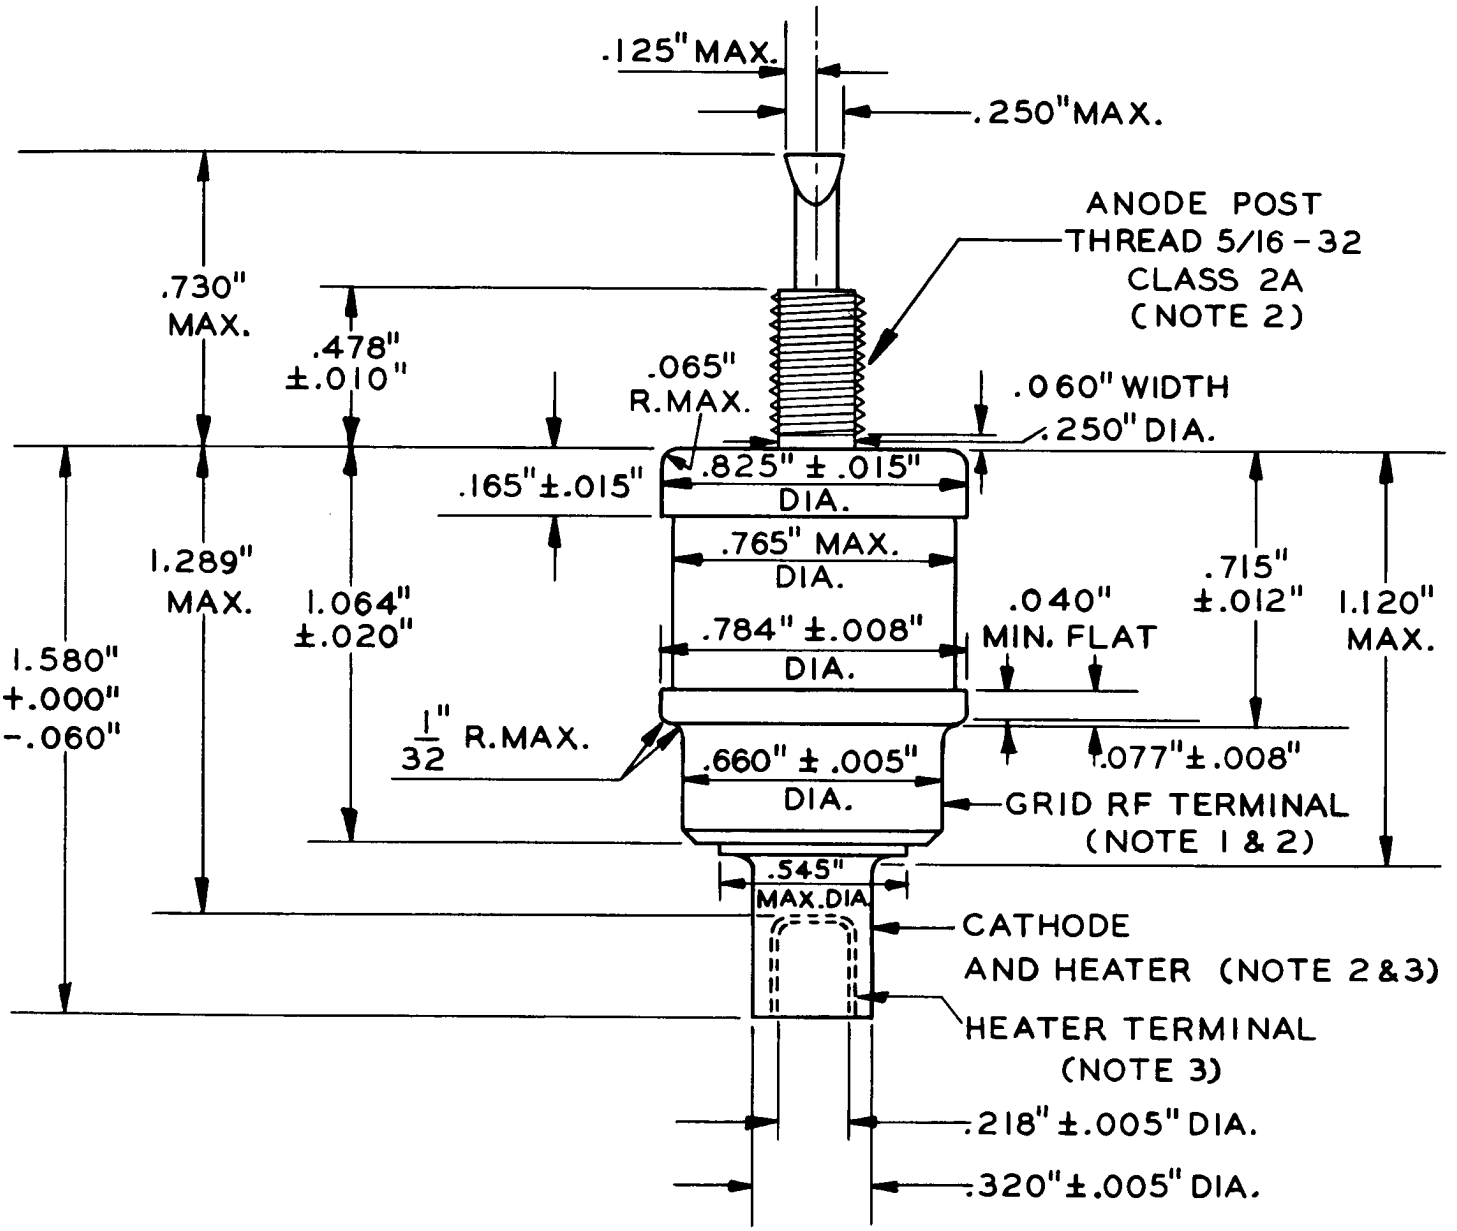
‡ Heater current of a bogey tube at Ef = 6.3 volts.

§ Measured in a special shielded socket.

¶ Modulation essentially negative may be used if the positive peak of the audio-frequency envelope does not exceed 115 percent of the carrier conditions.

With an adequate heat sink, the maximum dissipation rating is 100 watts.

Δ With an adequate heat sink, the maximum dissipation rating is 70 watts.



§§ An adequate heat sink must be provided.

‡‡ Where long life and reliable operation are important, lower envelope temperatures should be used.

** For modulation factors less than 1.0, a higher d-c plate voltage may be used if the sum of the peak positive audio voltage and the d-c plate voltage does not exceed 1200 volts.

¶¶ Adjusted for Ib = 75 milliamperes.

OUTLINE
A-0897

NOTES:

1. Solder not to extend radially beyond grid RF terminal.
2. Axis of threaded section shall be concentric with surface of Cathode-Fil. and Grid to within .020" T.I.R.. T.I.R. to be measured on cathode and grid contact areas within ±.040" of center of each area.
3. Total indicated runout of the heater-contact surface with respect to the cathode-contact surface shall not exceed 0.012".

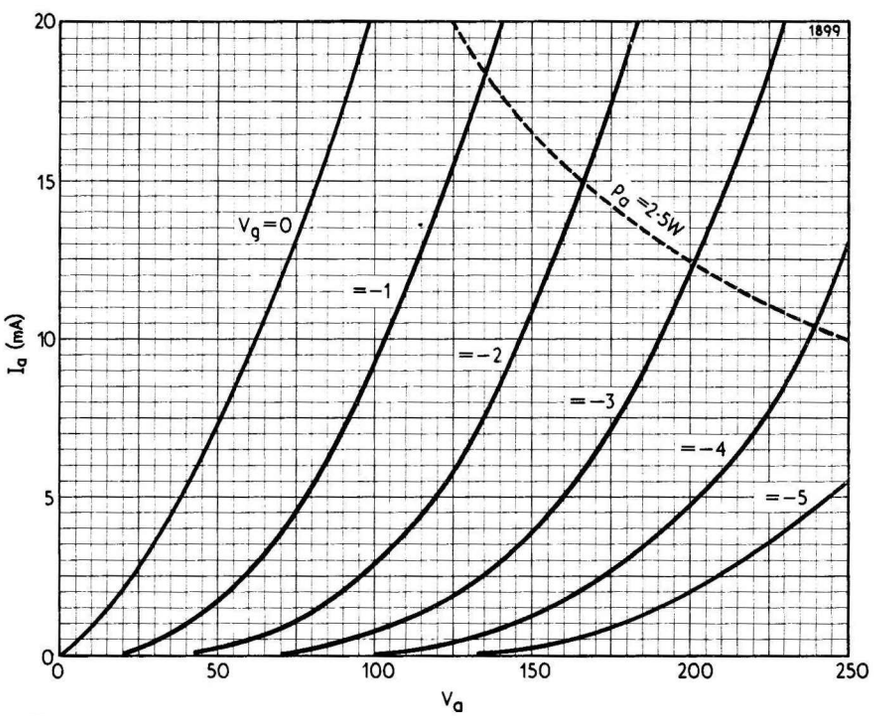
CHARACTERISTICS

V_a	150	V
I_a	10	mA
V_g	−2.2 (approx)	V
g_m	8.5	mA/V
μ	45	
r_{eq} noise ref g	500	Ω
*r_{in} (45 Mc/s)	40	kΩ
*c_{g-all} (45 Mc/s)	5	pF
Noise factor (45 Mc/s)	1.9	dB

*Measured with anode decoupled to cathode.



INSTALLATION

The valve may be mounted in any position.

A separate screening can should be used when the application demands.

Free air circulation around the bulb is preferable.

The temperature of the hottest part of the bulb must not exceed 220°C.

Printed in England

THE M-O VALVE
COMPANY LIMITED

A2087

GEC

VHF
NOISE GENERATOR DIODE

BRIEF DATA

A VHF noise generator diode with a tungsten filament. The A2087 is a commercial equivalent of the CV2171.

FILAMENT

*Filament voltage range	0 – 4.3	V
Filament current (approx at V_f = 4.3 V)	0.6	A

*The saturated anode current is regulated by variation of the filament voltage. With a 6.3 V filament supply, a variable series resistor of 10 Ω max. will be suitable for most purposes.

MAXIMUM RATINGS

Anode voltage	200	V
Anode current	20	mA
Anode dissipation	2	W
Filament voltage	4.8	V

CHARACTERISTICS

Anode voltage	40	V
Saturated anode current (approx)	7	mA
Filament voltage (approx)	3.7	V

CAPACITANCES (measured on a cold valve fitted with external shield)

Anode to filament (approx)	1.35	pF
*Anode to all (approx)	2.7	pF

*Includes capacitance to filament, pins 2 & 7 and external shield.

A member of the GEC Group of Companies
April 1977
Issue 3
© 1977 The M-O Valve Co. Ltd.

TYPICAL OPERATION

Noise Diode for use up to 220 MHz

Anode voltage	100	100	100	V
Saturated anode current range	0–20	0–20	0–20	mA
Filament voltage range (approx)	0–4.3	0–4.3	0–4.3	V
*Source resistance	50	70	300	Ω
*Noise factor measurement range (approx)	0–13	0–14.5	0–20.8	dB

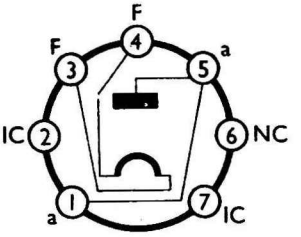
*When measuring receiver noise factor, using with the diode a source resistance R_s (to match the receiver input) and the technique of setting the value of $I_{a(sat)}$ to double the noise output power to the receiver detector, the range of noise factor that can be measured with a given value of R_s is as shown.

Then, noise factor = $10 \log_{10} (20 I_a R_s)$ dB,
where I_a is the diode saturated anode current in amperes and R_s is the source resistance in ohms.

INSTALLATION

The valve can be mounted in any position.

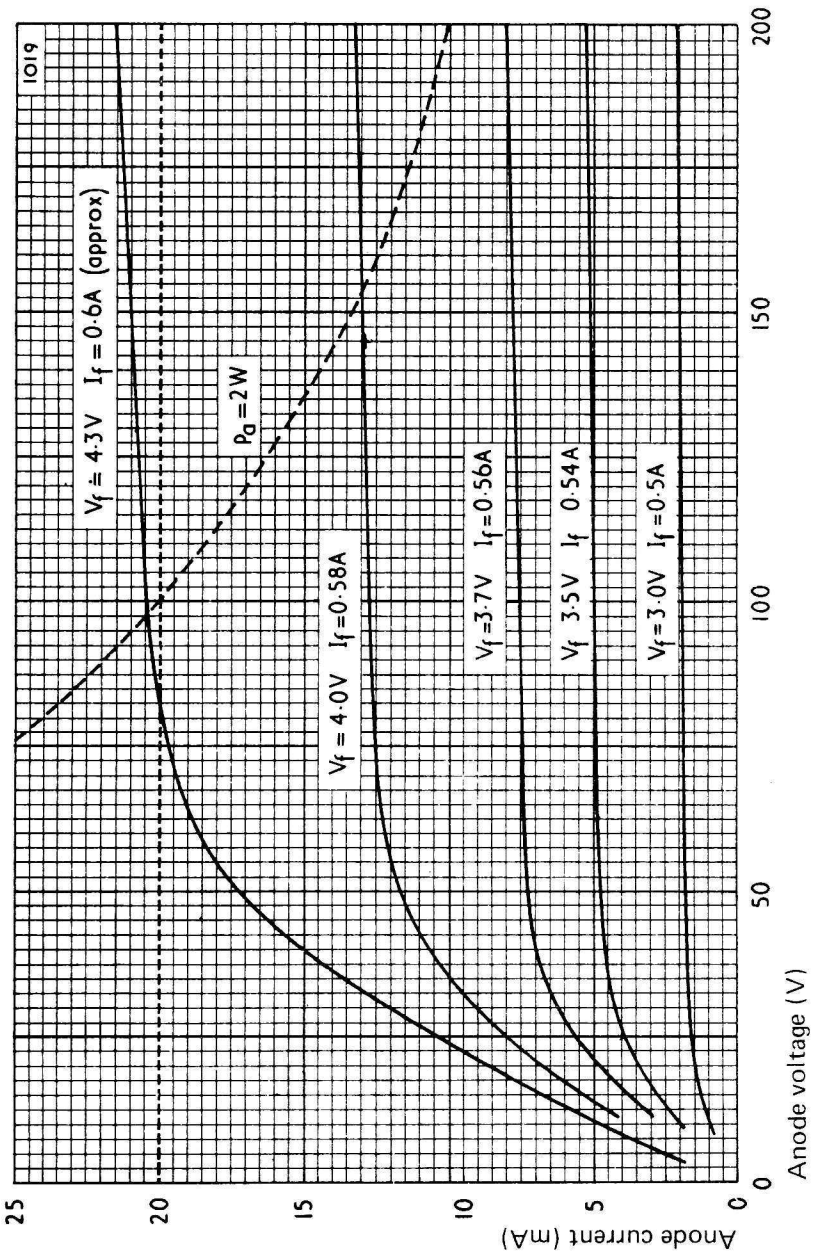
A screening canister, which also serves as a retainer, is necessary.



Free air circulation around the canister is preferable. The temperature of the hottest part of the bulb must not exceed 200 °C.

This valve has been designed to give a life of 1,000–2,000 hours operating at a saturated current of 5 mA. With a saturated current of 20 mA the life is approximately 100 hours.

No correction of the noise factor for electron transit time when measured as above is necessary for use up to 220 MHz.



Whilst M-OV has taken care to ensure the accuracy of the information contained herein it accepts no responsibility for the consequences of any use thereof and also reserves the right to change the specification of goods without notice.
M-OV accepts no liability beyond that set out in its standard conditions of sale in respect of infringement of third party patents arising from the use of tubes or other devices in accordance with information contained herein.

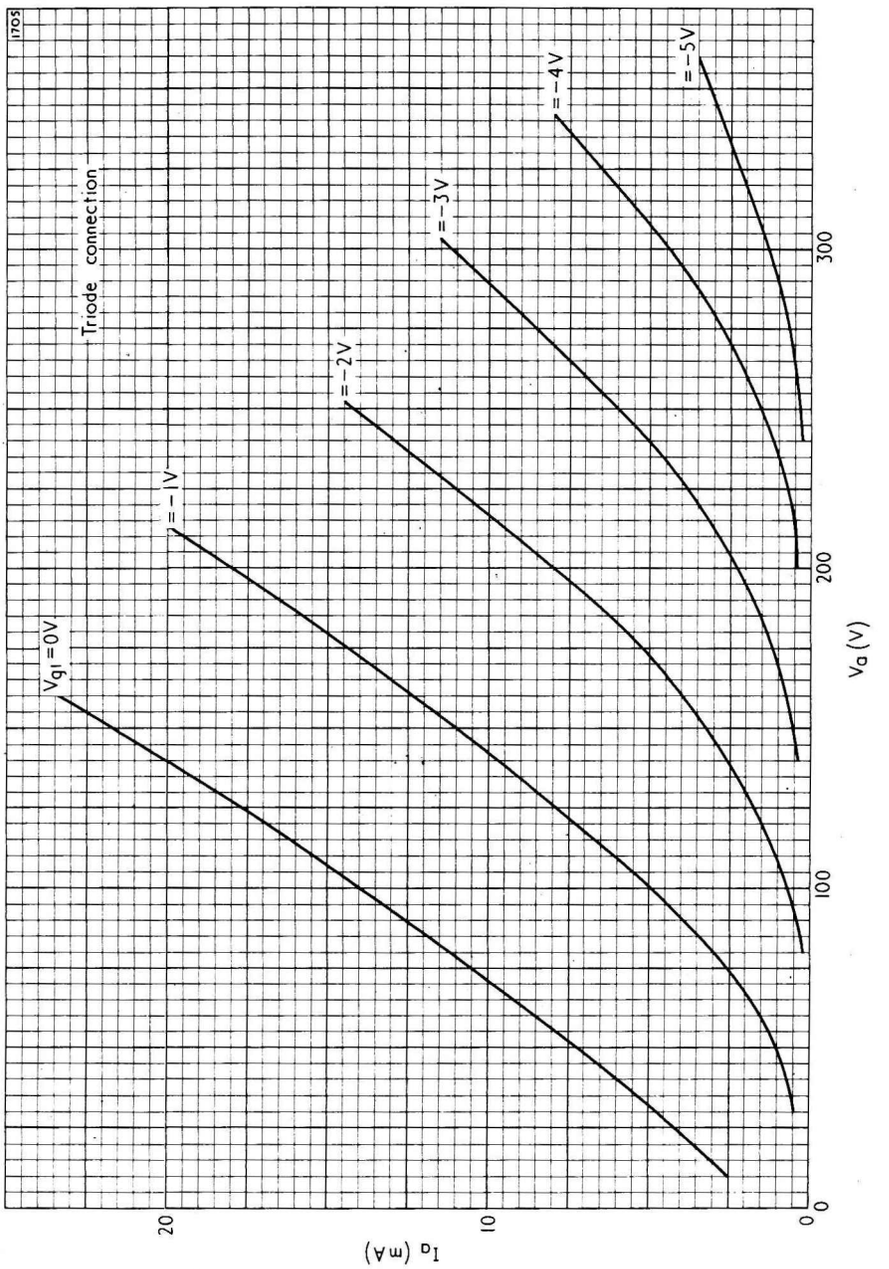
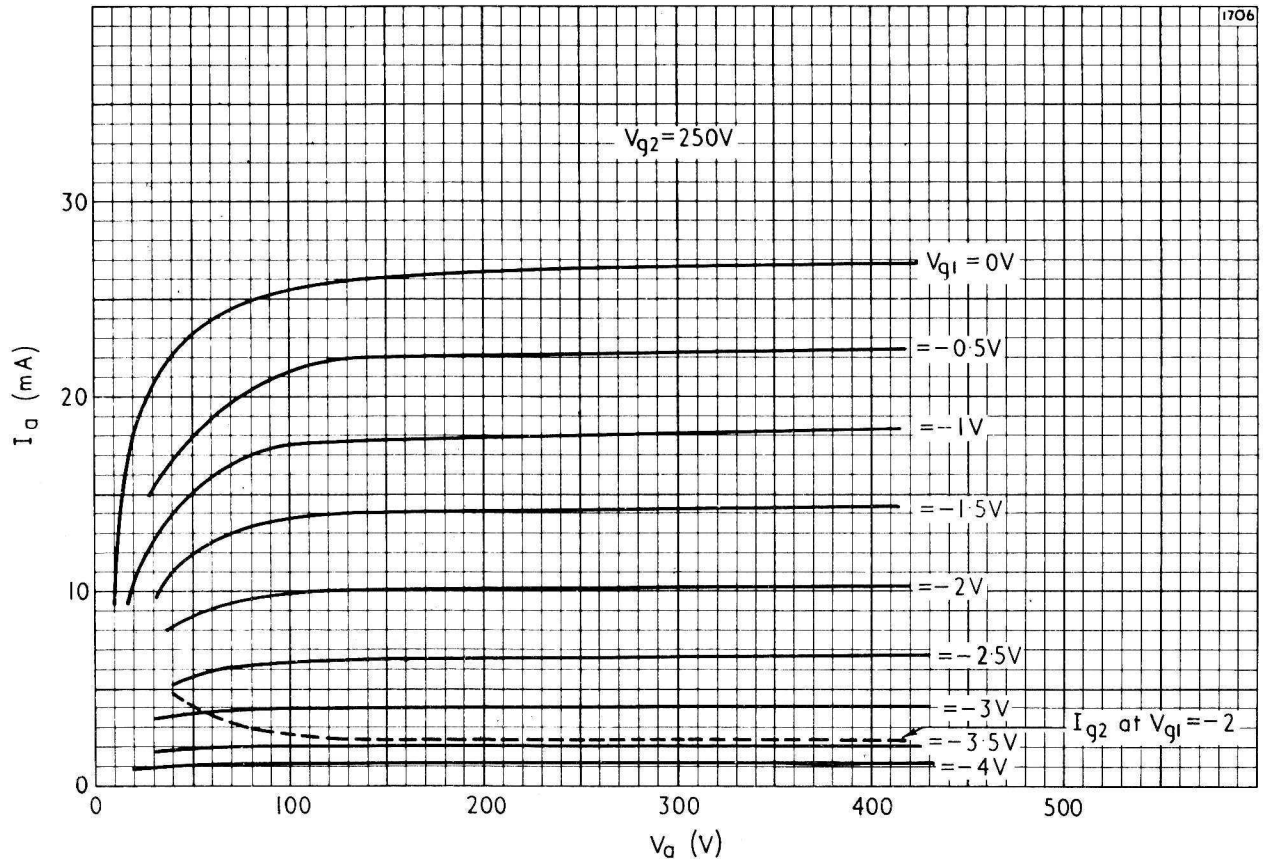
*These tests are performed on a sample basis only, and the figures given are of the average spread.

LIFE PERFORMANCE

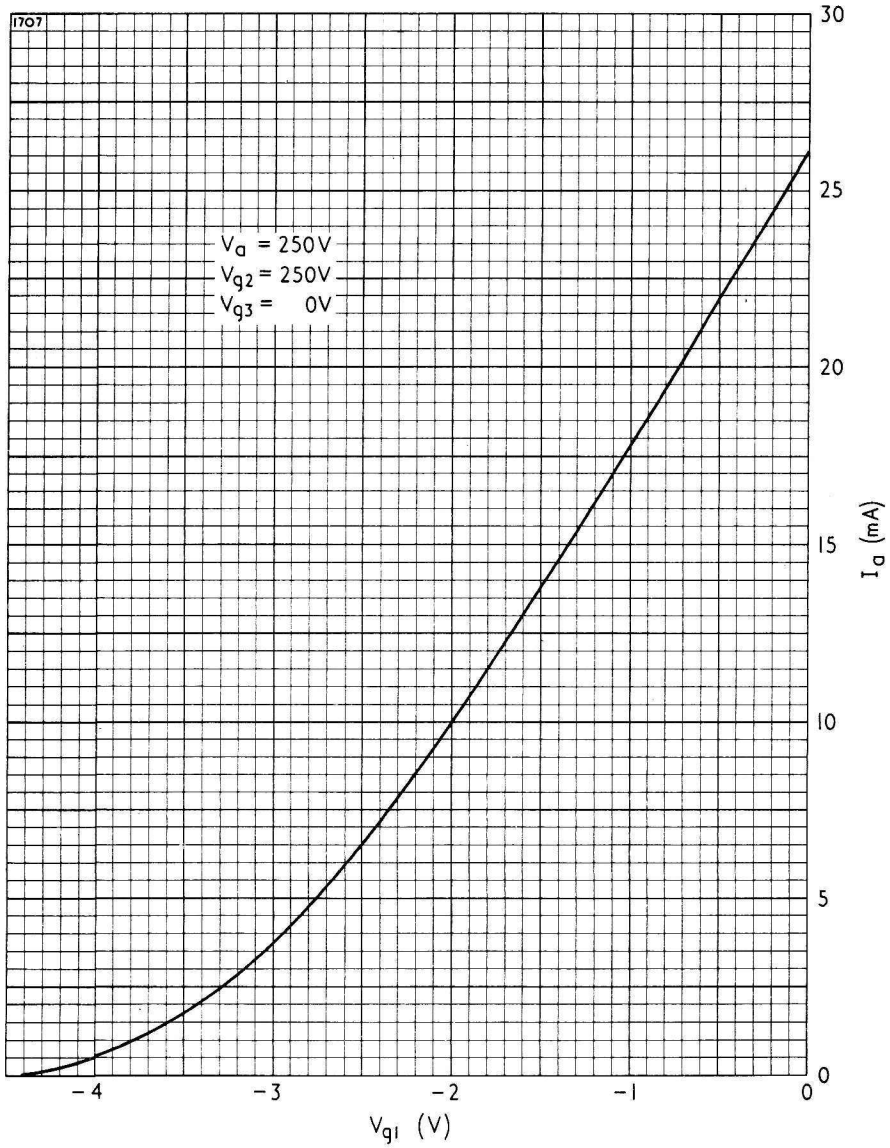
The average life expectancy of the A3064 is at least 10,000 hours. In order to obtain maximum life, the valve must be operated within the ratings given on page 1. The environment must be a static one and the valve must not be switched more than 12 times in 24 hours. The life expectancy may be reduced if conditions other than those specified are imposed on the valve, and will be reduced appreciably if the absolute maximum ratings are exceeded. Both reliability and performance will be jeopardised if heater voltage ratings are exceeded. Life and reliability are directly related to the degree to which regulation of heater voltage is maintained at its centre rated value. Attention should also be paid to the recommendations of the British Standard Code of Practice CP1005 "The Use of Electronic Valves".



A valve is considered to have reached the end of life when it is either inoperative, or one or more of its characteristics has reached the following values :

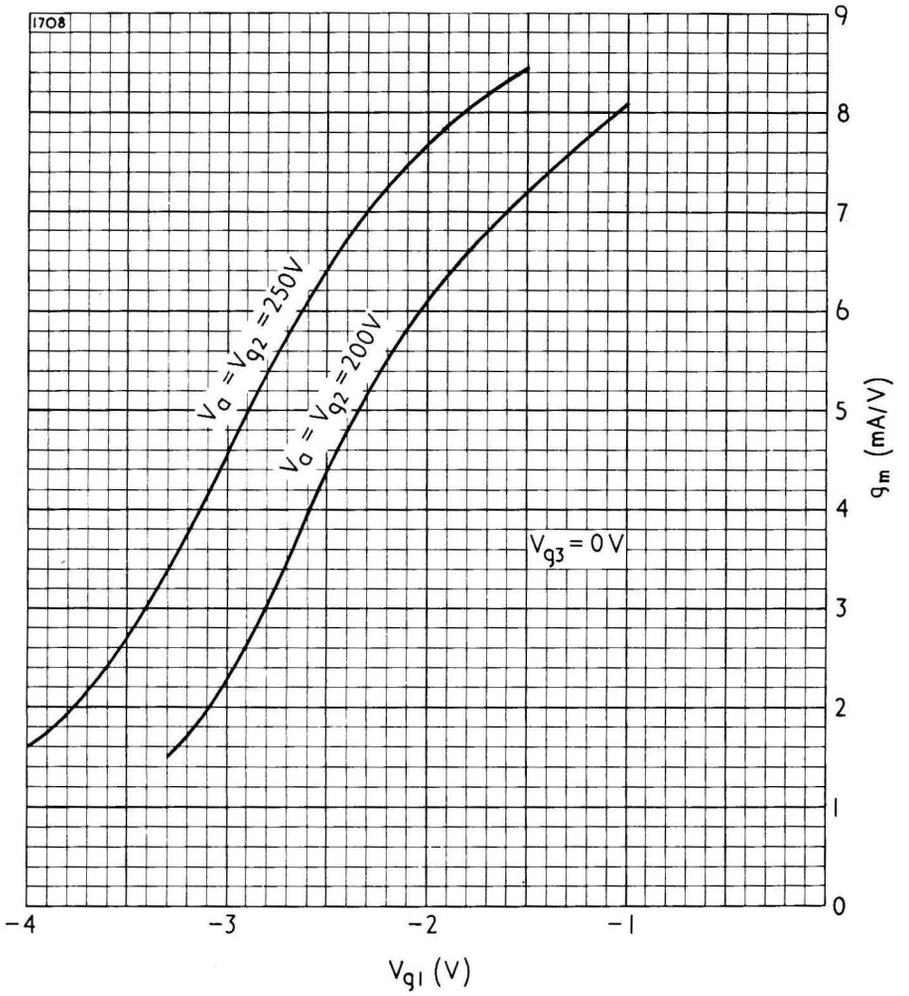


I_a	5.25	mA
g_m	4.9	mA/V
$-I_{g1}$	3.0	μA
I_{hk} (V_{hk} ±100)	20	μA



measured as "Characteristic Spread".

INSTALLATION



The valve may be mounted in any position.

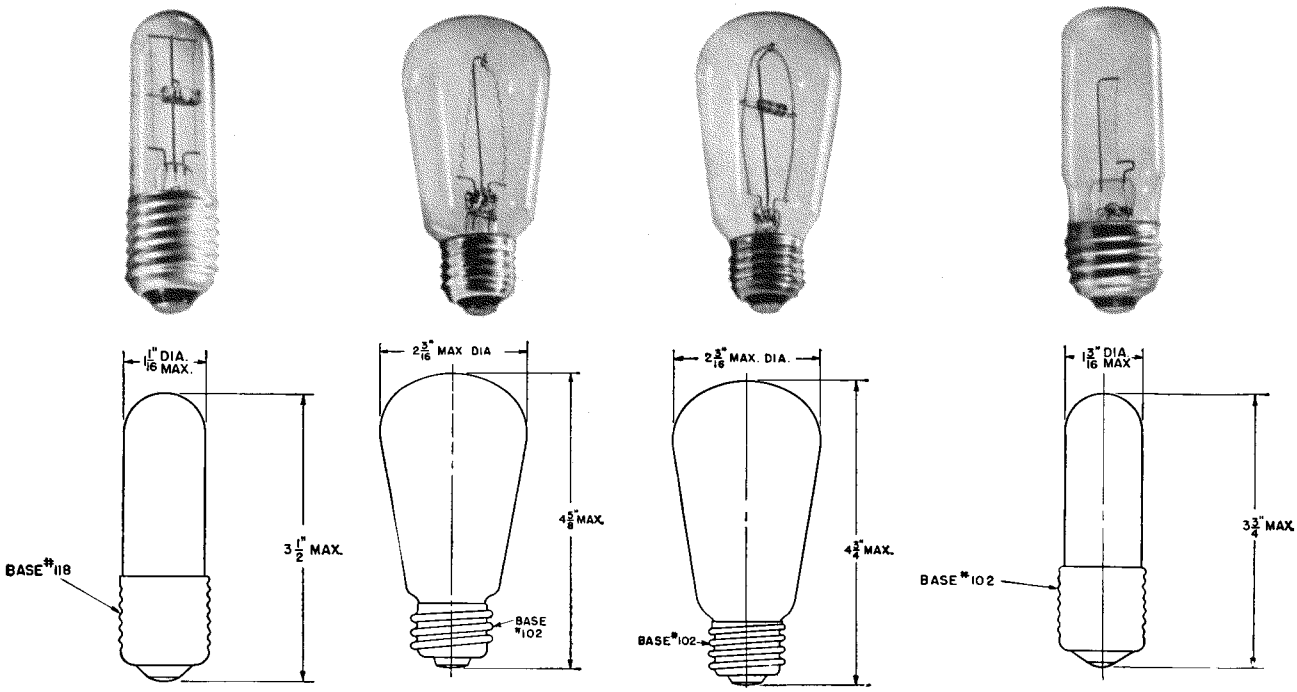
GENERAL ELECTRIC

BALLAST TUBES

DESCRIPTION



A ballast tube is essentially a constant-current device. It is a resistor whose resistance, at a certain critical temperature, varies with temperature so rapidly that, as the voltage across the tube varies, the current remains practically constant. The operation is the same on either alternating or direct current. Its function is to maintain a constant average current.

All ballast tubes now manufactured have been designed for a specific application and, as a result have non-uniform ratings. Because of the wide range of voltage and current ratings possible, no attempt has been made to manufacture a standard line. Ballast tubes may, however, be used in parallel or with shunting resistors across the load to increase or decrease the current rating, or with series resistors to increase the voltage rating. These methods are described under the section titled "Operation."

RATINGS AND DATA

In rating a ballast tube, the voltage range over which the current is nearly constant is given together with a maximum and minimum current. The upper limit of the voltage range is to be considered the maximum voltage at which the tube may be operated. Over the voltage range the current may vary two per cent above or below its average value. The average current of individual tubes may be as much as two per cent above or below the average current of the entire production. Therefore, considering change of current with life and any other factors which may enter, the variation of current in a circuit using ballast tubes may be as much as five per cent above or below the average. The limits given in the tube ratings cover these factors.

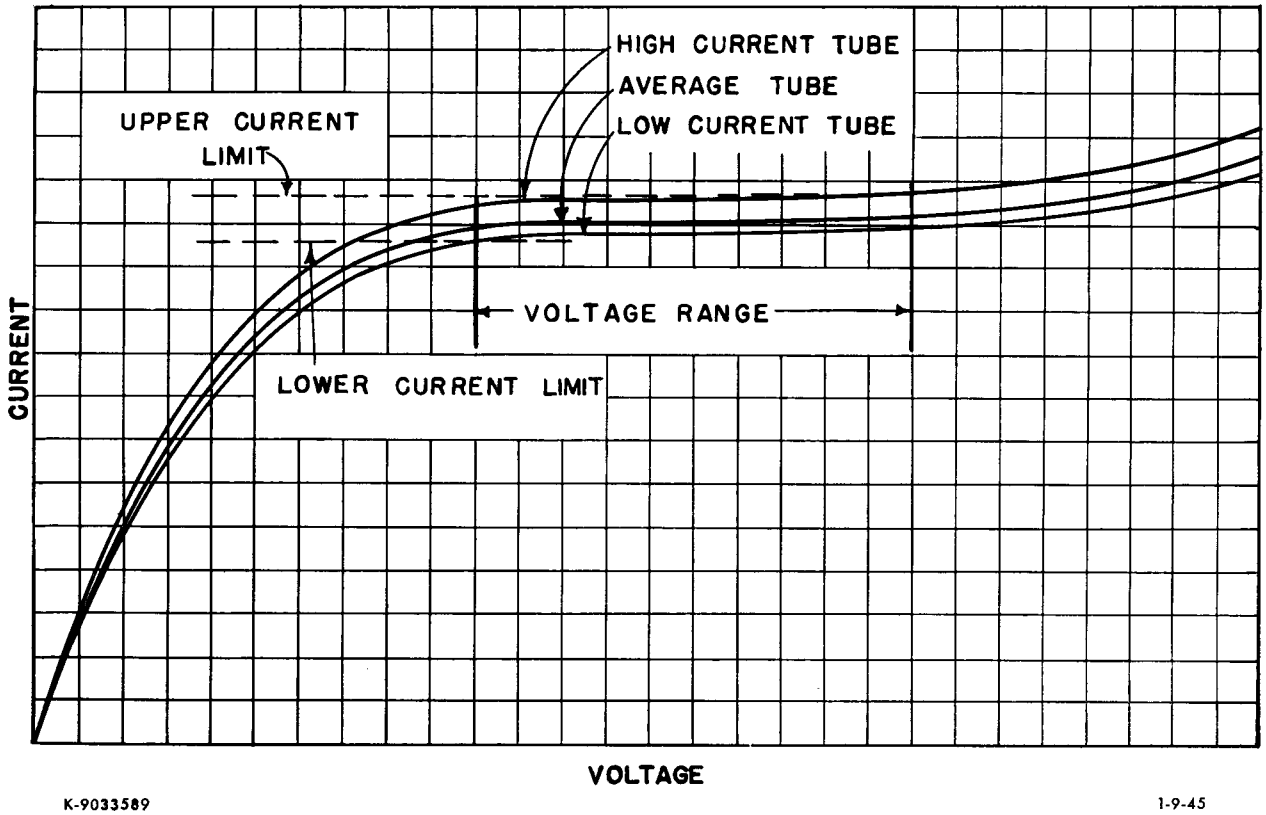
INSTALLATION



The ballast tube should be mounted, with the base down, in an enclosure rigid enough to stop flying glass since, should the tube develop an air leak, the mixture of oxygen with the hydrogen contained in the tube might become of the right proportion to explode. The envelope becomes quite hot during operation, and free circulation of air must be allowed in order to keep the temperature of the air near the tube below 150 F. Marked changes in envelope temperature will cause a change in the current. Since the entire load current must pass through the ballast tube, the socket and connections to it must be clean and make good contact to prevent heating at these points.

OPERATION

The operation of the tube is shown by the characteristic curves in Fig. 1. As the voltage across the filament rises from zero, the resistance of the tube increases slowly in the same manner as most metals. As the lower end of the operating range is reached, the resistance of the filament increases quite rapidly with temperature, so that further increase in voltage causes practically no further increase in current. As the upper end of the operating range is reached, the resistance again becomes nearly constant. A still further increase in voltage causes an almost proportional increase in current as illustrated in the curves of Fig. 1.

This operation of the tube can be seen by observing the filament. As the voltage across the tube is increased from zero and approaches the lower end of the operating range, a small section in the middle of the filament will become red hot. As the voltage is increased further, the length of this red-hot section increases until the entire filament is visibly hot. This represents the end of the operating range and any increase in voltage will overheat and damage the tube. Operating the tube above the upper limit of voltage will result in excessive expansion and contraction of the filament as the voltage varies; this will cause the wire to stretch out the coils of the filament or to knot, which will increase the current and speed up the destructive process already started, resulting, shortly, in filament burn-out.

If a steady voltage of a value in the middle of the operating range is applied to the tube continuously, its life will be tens of thousands of hours. Opening and closing the circuit with the resulting lengthen-

K-9033589 1-9-45

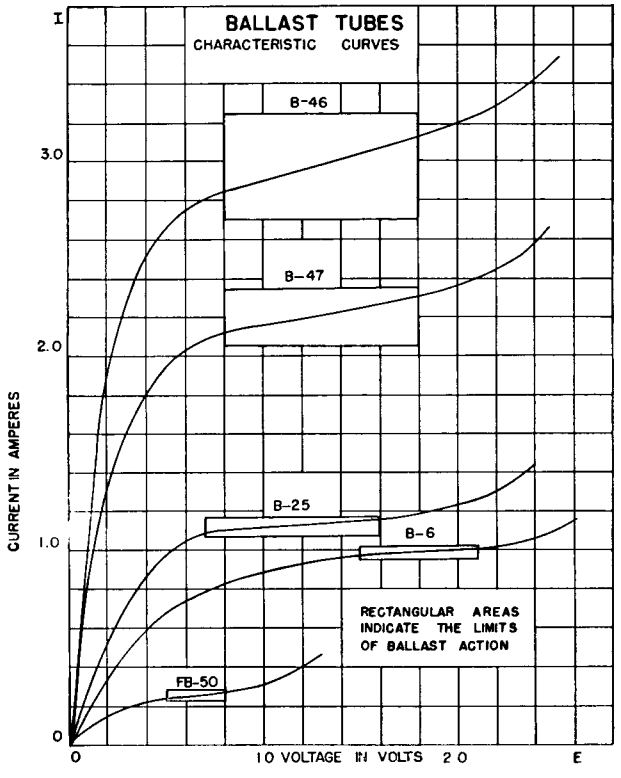


Fig. 1—Typical Ballast Tube Characteristics

ing and shortening of the filament greatly reduces the life of the tube. If full voltage is applied to the tube, the circuit may be opened and closed only a few hundred times before the current is outside the limits or the filament is burned out. Thus the life of the tube will be determined entirely by its duty cycle.

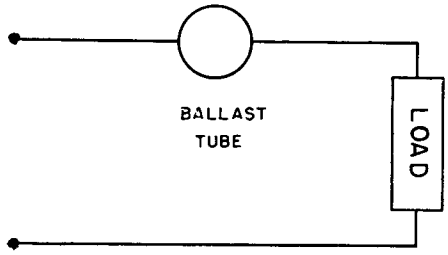
Because of the large thermal inertia of the tube, the temperature does not reach its final value immediately when the circuit is closed or when the voltage changes. Since the cold resistance of the filament is quite low, when the circuit is first closed the initial current may be several times the final value.

After a few seconds, however, the current will have fallen to within 25 per cent of the final value, and from 15 seconds to several minutes, depending upon the size of the tube, will be required for the current to reach a steady state. The real function of a ballast tube is to maintain a constant average current.

In Fig. 1 three curves are given to show the variation to be expected between tubes of a given rating. By choosing the proper coordinates, these curves are approximate for any ballast tube. Individual tubes may maintain the current to less than the range shown, but in any particular application variations up to plus or minus five per cent of the average may be expected. Typical characteristic curves indicating the limits of ballast action for the various types of ballast tubes are shown in Fig. 1A at the right.

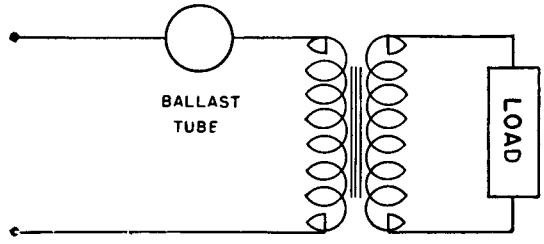
K-9033550 12-30-44

Fig. 1A



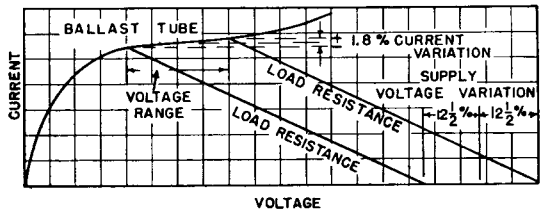
APPLICATION CIRCUITS#

The commonest use of the ballast tube is to place it directly in series with the load as shown in Fig. 2 and Fig. 3.



The graphical representation of the current and voltages in the circuit is shown in Fig. 4.

When voltage is applied, the current which flows is determined by the intersection of the load characteristic and the tube characteristic. As the supply voltage varies the current remains practically constant. The load voltage remains practically constant because the tube voltage varies by an amount proportional to the supply-voltage variation. The tube used should have a voltage range equal to the variation in supply voltage.



#Circuits shown in ETI-194 are examples of possible tube applications and the description and illustration of them does not convey to the purchase of tubes any license under patent rights of General Electric Company

K-9033579 1-1-45

Fig. 4—Ballast Tube in Series with Load

K-9033580 1-1-45

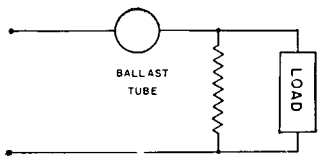

Fig. 5—Vector Diagram For Inductive Load

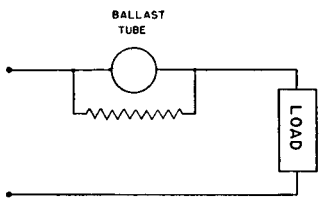
A ballast tube may be used with inductive loads as well as with pure-resistance loads. Fig. 5 shows the vector diagram for such a load. The vector *OE* represents the normal supply voltage, while the vectors *OB* and *BE* represent the normal load and ballast-tube voltages, respectively. *OH* is the normal current. As the supply voltage decreases to *OD* or increases to *OF*, the ballast-tube voltage decreases to AD or increases to CF. This maintains the load voltage between OA and OC and the current between OG and OJ.

If it is necessary to use a tube whose current rating is too high or too low, either the load or the tube, as the case may be, may be bridged with a resistor to carry the excess or additional current. Figs. 6 and 7 show these two connections.



The operation of the circuit shown in Fig. 6 is identical with that shown in Fig. 2, the resistor being considered part of the load. This circuit is also recommended where close adjustment of the load voltage or current is required. The circuit shown in Fig. 7 is similar in operation except that the shunt current through the resistor, as shown in Fig. 8 increasing directly with voltage, spoils somewhat the regulation of the tube.

In the latter case, the higher the value of shunt resistors used across the ballast tube, the better the regulation. This connection is not recommended except in cases where close regulation is unnecessary.

(Not recommended)

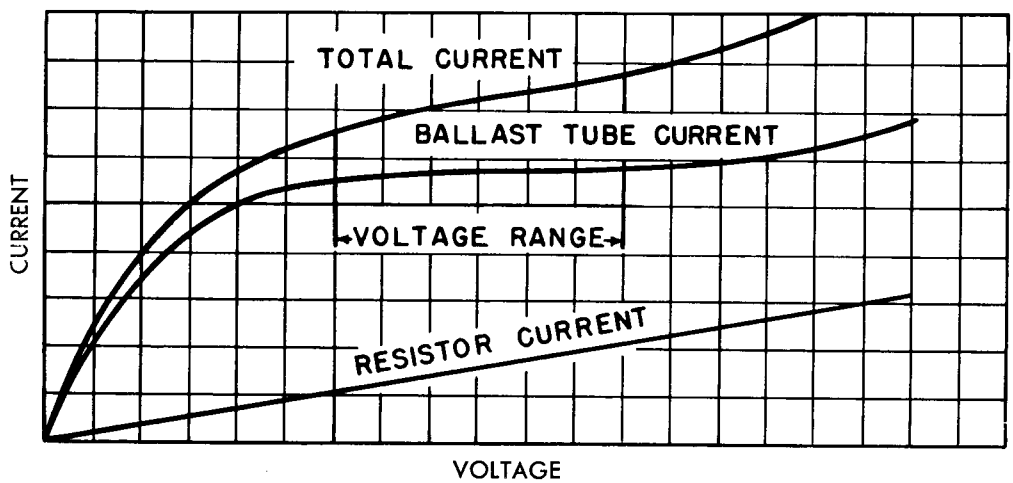

Fig. 8—Resistor Across Ballast Tube

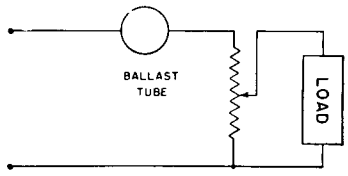
K-9033581 1-1-45

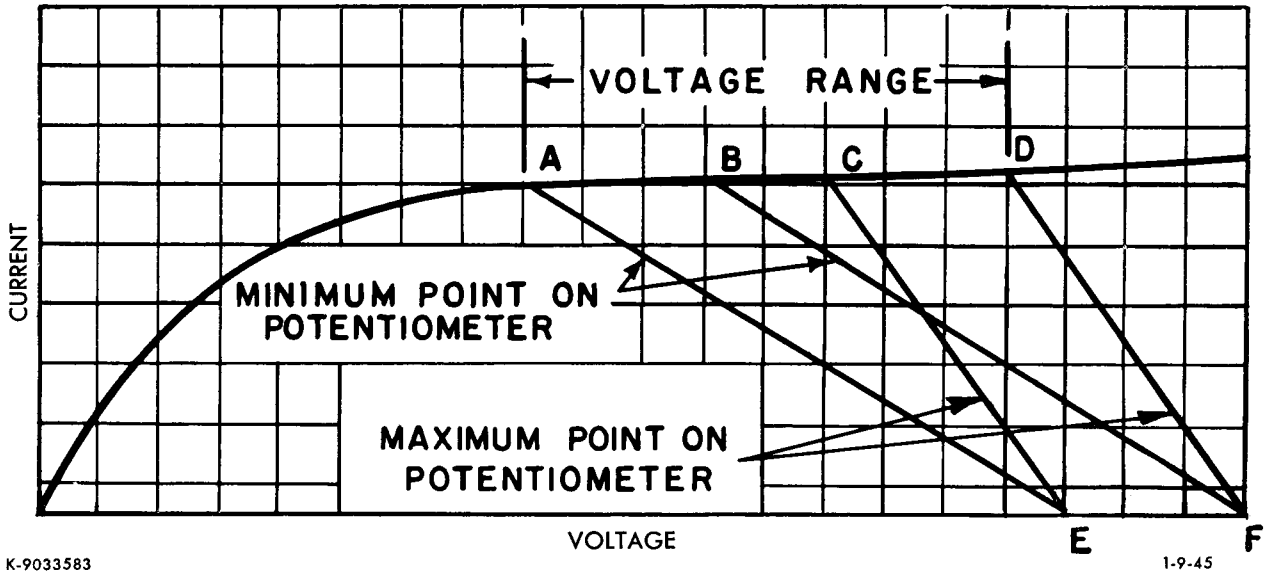


APPLICATION CIRCUITS (Contd.)

The ballast tube may be used to maintain constant current in a circuit requiring variation of the load. A suggested circuit is shown in Fig. 9.

Since the voltage across the ballast tube will vary with both the line voltage and load resistance (the potentiometer being considered part of the load) a greater voltage range will be required, and the ballast tube will use a greater percentage of power See Fig. 10 below.

The minimum voltage across the ballast tube will occur with minimum supply voltage and with the load adjusted to the minimum point on the potentiometer. The maximum voltage across the ballast tube will occur with the maximum supply voltage and with the load adjusted to the maximum point on the potentiometer. Since this circuit draws a constant current from the line, varying the potentiometer will not cause a variation in supply voltage to other apparatus on the line.



Ballast tubes may be used in parallel provided their voltage ranges are equal or nearly so. If their voltage ranges are unequal, good ballasting will occur only over that part of the voltage range which is included by both tubes. The current for any voltage will be the sum of the currents in both tubes at that voltage.

K-9033582 1-9-45

Fig. 9—Circuit for Varying Load Voltage

Ballast tubes cannot be used in series unless their current-voltage characteristics are identical. This can be shown by referring to Fig. 1. If two tubes, one having the maximum current and one the minimum for a particular rating, are used in series the current will be the same in both tubes at all times. At the value at which the higher-current tube starts to ballast, the lower-current tube is operating above its ballasting range and hence is over-loaded. Thus, the safe operating range of the combination is only that of the lower current tube.

I_f (at V_f=6V)	1·15 (approx)	A

The value of the saturated anode current is regulated by variation of the filament voltage.

MAXIMUM RATINGS (Absolute)

V_a	200	V
I_a	85	mA
p_a	3·5	W
V_f	6	V

CAPACITANCES (Measured on a cold unscreened valve)

$c_{a-f(max)}$	3	pF

CHARACTERISTICS

V_a	50	V
$I_{a(sat)}$ (approx)	50	mA
V_f (approx)	5·6	V

TYPICAL OPERATION

Noise diode for use up to 220 Mc/s

When measuring receiver noise factor using with the diode a source resistance R_{source} (to match the receiver input) and the technique of setting the value of $I_{a(sat)}$ to double the noise output power from the receiver detector, the range of noise factor that can be measured with a given value of R_{source} is as shown.

Then, noise factor = 10 $\log_{10}$ ($I_{a(sat)} \times R_{source}$) db.

No correction of noise factor measured is necessary up to 220 Mc/s.

V_a	50	50	50	V
$I_{a(sat)}$ (range)	0—70	0—70	0—70	mA
V_f (range) (approx)	0—6	0—6	0—6	V
R_{source}	50	70	300	Ω
Noise Factor Measurement (range) (approx)	18·4	19·9	26·2	db

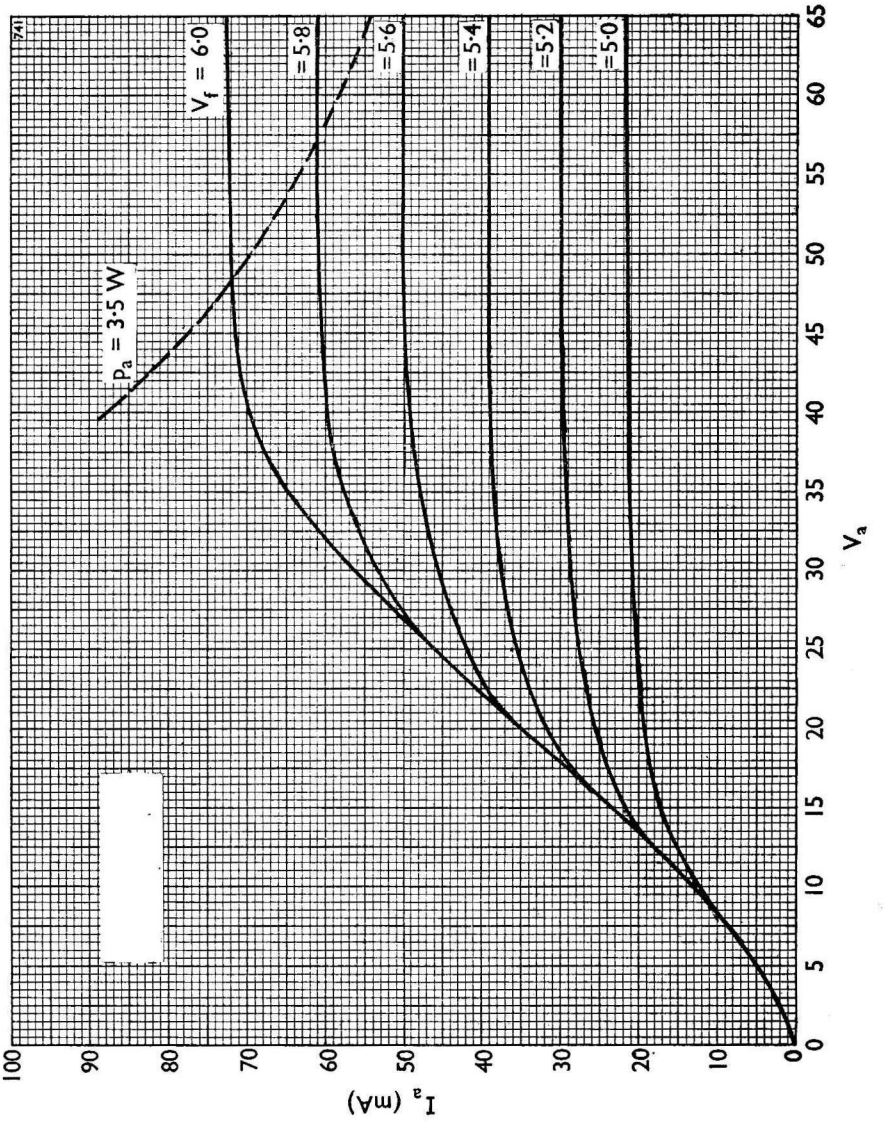
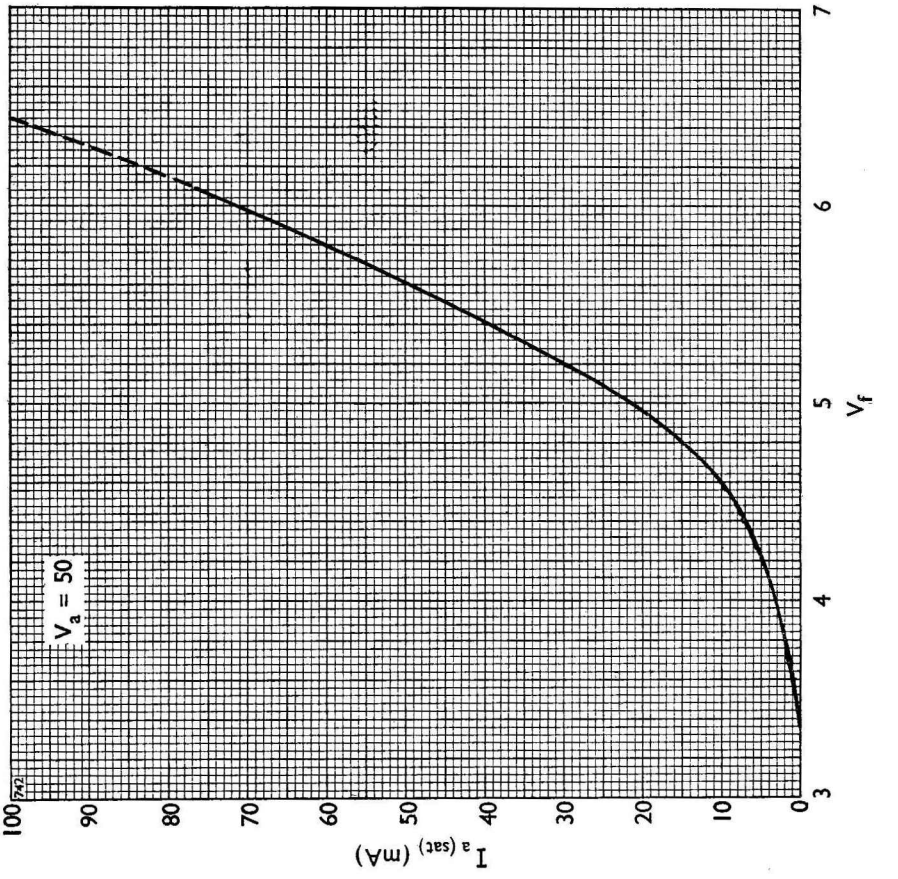
Head Office : Magnet House . Kingsway . London . W.C. 2

AUGUST, 1958

CV2398

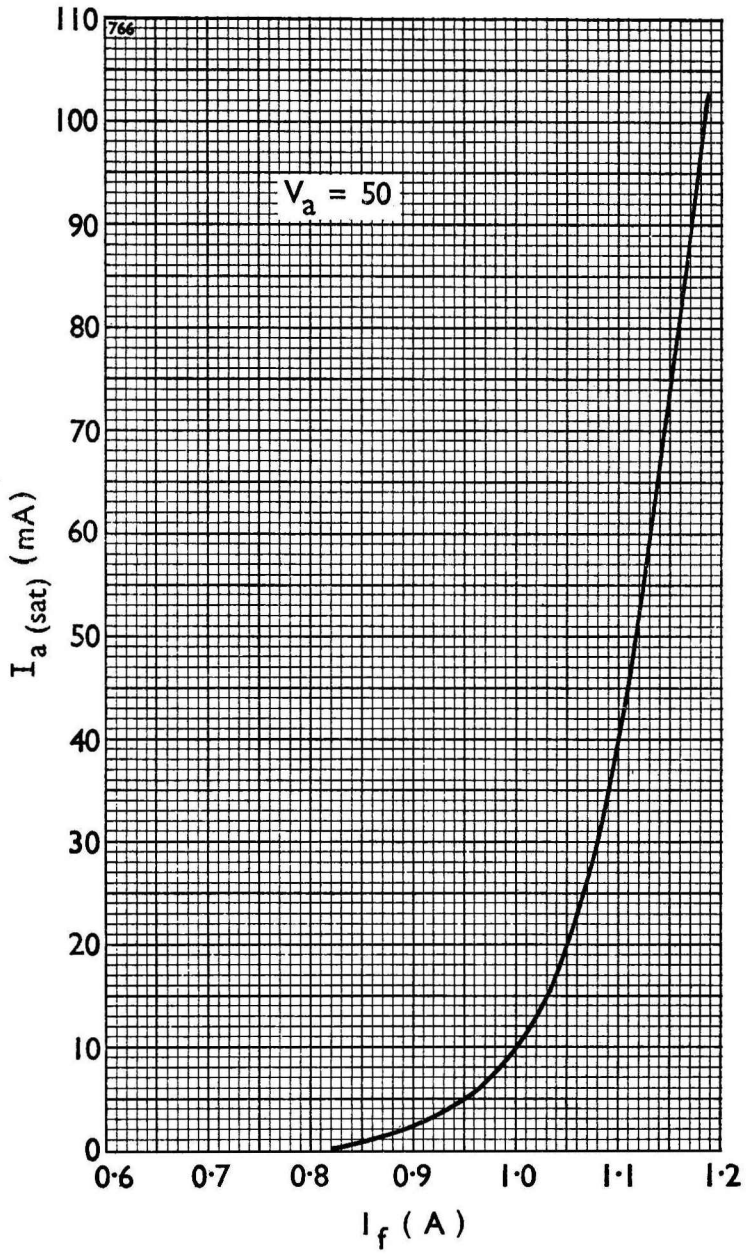


INSTALLATION



The valve can be mounted in any position.

A screening can, which also serves as a retainer, is necessary.



Free air circulation around the can is preferable. The temperature of the hottest part of the bulb must not exceed 200°C.

Leads should not be soldered or bent less than 3 mm from the base.

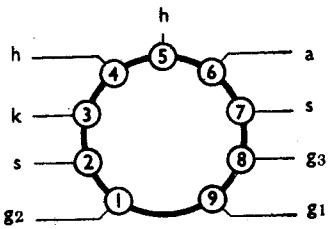
†Following valve grid resistor.

INSTALLATION

The valve may be mounted in any position. The use of a retaining device is recommended. The valve is internally screened.

TESTING

These valves are manufactured in discrete lots, under carefully controlled conditions. Each lot is very comprehensively tested for electrical and mechanical properties in a manner specified by the relevant Government Authority.



The limits imposed in the electrical tests are usually closer than those used in normal domestic or commercial valve testing, and include control on the spread of characteristic parameters.

Random samples are also taken from each lot, and subjected to specified destructive and electrical and mechanical life tests.

The lot is only released if it passes all the above tests, including the life tests.

The careful control of manufacture and the comprehensive testing and lot release system are designed to reduce microphony, the spread in electrical properties and the incidence of early failures, and to provide known life performance within the specified electrical and mechanical maximum ratings.

I_g (R_{g-k} = 500kΩ)	3.0 (max)‡	μA
V_{h-k}	±250	V
I_{h-k}	30 (max)‡	μA

*Measured in an approved manner.

†Every valve tested.

‡These tests are performed on an agreed sample basis.

§ Δg_m is defined here as:-

$$\Delta g_m = \frac{(g_m \text{ at } V_h = 6.3V) - (g_m \text{ at } V_h = 5.7V)}{(g_m \text{ at } V_h = 6.3V)} \times 100\%$$

// t_{hk} is defined here as the time taken for I_a to rise to 100mA, from switching on the heater of a valve whose heater has not been operated for at least two hours. The impedance of the heater voltage supply must be low enough to ensure that V_h = 6.3V throughout the heating time.

INSTALLATION

The valve may be mounted in any position.

TESTING

These valves are manufactured in discrete lots, under carefully controlled conditions. Each lot is very comprehensively tested for electrical and mechanical properties in a manner specified by the relevant Government Authority.

The limits imposed in the electrical tests are usually closer than those used in normal domestic or commercial valve testing and include control on the spread of characteristic parameters.

Random samples are also taken from each lot and subjected to specified destructive electrical and mechanical life test.

The lot is only released if it passes all the above tests, including the life test.

The careful control of manufacture and the comprehensive testing and lot release system are designed to reduce microphony, the spread in electrical properties, the incidence of early failures and provide known life performance within the specified electrical and mechanical maximum ratings. An article in British Communications and Electronics (April 1958) by R. Brewer of the G.E.C. Research Laboratories entitled "The Life Test Contribution to the Improvement of Valve Reliability" discusses these points more fully. Reprints can be supplied on request.

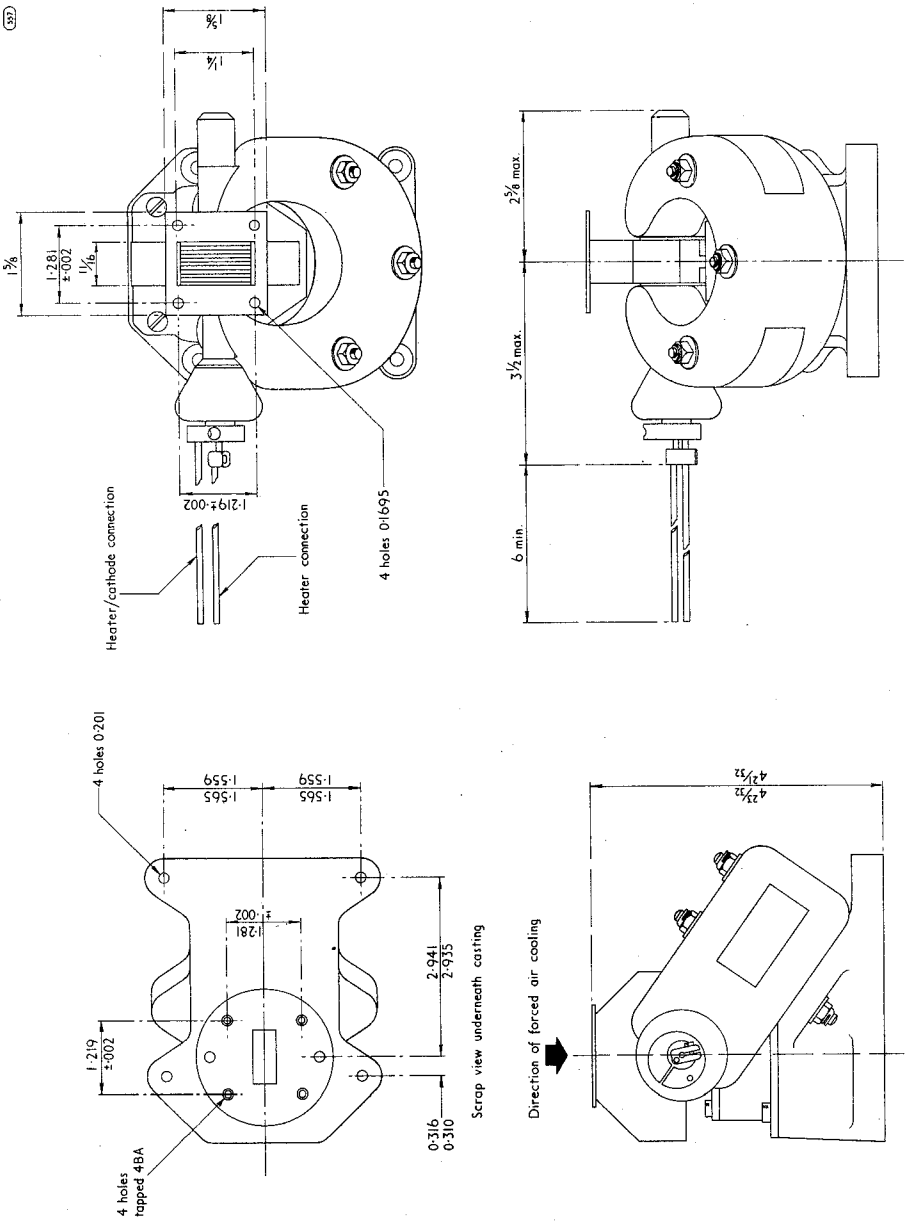
Minor lobes	-12	-10	dB
Pushing figure	0.2	0.2	$Mc/s(A)^{-1}$

*Rate of rise of applied voltage is defined here as the value of $\frac{dv_a}{dt}$ between 80% and 100% of the peak amplitude of the voltage pulse.

INSTALLATION



The valve may be mounted in any position.

The r.f. output is by standard waveguide WG16 (0.4 x 0.9 in. i.d.) to connect to a suitable square choke flange.

The valve must be forced air cooled at 15 c.f.m. through the cooling duct, so that the maximum temperature ratings are not exceeded.

The total weight of the valve is about $7\frac{1}{2}$ lb.

As there is a strong magnetic field in the vicinity of the valve, care must be taken to keep magnetic materials at least two inches away from it.

All dimensions are in inches

THE M-O VALVE CO. LTD. · BROOK GREEN · LONDON · W.6
a subsidiary of
THE GENERAL ELECTRIC CO. LTD. OF ENGLAND

JANUARY, 1961

CIRCUIT DESIGN

The CV6055 is designed for use in coaxial circuits in which the anode is connected to the inner line. The performance data given was obtained with an anode/grid line of 59Ω characteristic impedance. The dimensions of the anode line and the line lengths required for a range of wavelengths are shown in fig. 3.

COOLING

For full rated anode dissipation in ambient temperatures up to 30°C, the air flow to the anode must be 5 cu. ft./min minimum at about 2 in. static water gauge.

The temperature of the glass to metal seals must not exceed 140°C. An air flow may be required to ensure this. The temperature may be checked with " Tempilac " paint, obtainable from J. M. Steel & Co. Ltd., 36 Kingsway, London, W.C.2.

INSTALLATION

The valve may be mounted in any position. Rigid connections must not be made to more than one electrode.

Line width (typical) 24 screen		0.4	mm

Measured by means of a shrinking raster at $I_b = 5\mu A$

DISPLAY CHARACTERISTICS (Typical Operation)

Pattern Distortion

With pattern correction applied to s, the edges of a test raster will lie between two concentric rectangles of 70mm x 50mm and 68mm x 48mm. The angle between x and y axes will be 90° ± 1° measured at face centre.

X Deflection Linearity

The deflection factor for a deflection of less than 75% of the useful scan will be equal to that for a deflection of 25% within approx 3%.

Spot Position

The focused and undeflected spot will fall within a square 10mm x 10mm centred at the geometric centre of the faceplate.

Orientation

Looking at the screen with pins 1 and 12 uppermost, a positive voltage applied to x1 will deflect the beam to the left and a positive voltage applied to y1 will deflect the beam upwards.

Minimum Scanned Area

x major axis	7.0	cm
y minor axis	5.0	cm

This area will be centred on a point which is within 3mm of the major and minor axes of the tube face.

Axis Alignment

The electrical x axis of the tube will lie within ±5° of the major axis of the faceplate, and may be aligned with this axis by means of the field from an axial coil placed about the cone of the tube in the region shown in the outline drawing. The maximum ampere turns required for axis alignment will be given by $11\sqrt{kV_{a4}}$.

MOUNTING

The tube may be mounted in any position but should not be supported by the base alone. It should preferably be held in a suitable rubber mask at the screen and by a clamp around the magnetic shield near the base. The socket should have sufficient freedom of movement to accommodate the maximum overall tube length and base orientation tolerances.

WEIGHT

The weight of the tube alone is 500gm (approx).

BASE CONNECTIONS

TYPICAL OPERATION (in coaxial oscillator as shown in fig. 4)

Frequency	500	MHz
DC anode voltage	300	V
DC anode current	100	mA
DC grid current	40	mA
Negative dc grid voltage	15	V
Load power	14	W

CIRCUIT DESIGN

The performance of the DET24 as an oscillator and an amplifier is shown in the curves of figs. 9 and 10. The circuits used to obtain this data are given in figs. 4 and 5 for the oscillator and amplifier respectively. In both cases the circuit elements consist of coaxial lines with the grid line common to input and output cavities.

The anode-grid and grid-cathode cavities are both tuned by means of movable bridges; if contact bridges are used, it is important that good contact is made with the tubes on which they slide. In order that bias may be used, a grid-cathode contact bridge must incorporate a capacitor. Both the need for this capacitor and the difficulties of reliable sliding contacts are avoided if non-contact bridges are used.

In the oscillator the position of the feedback probe depends upon the required wavelength and on the mode of operation of the tuned circuits. Probe positions are shown in fig. 4 for a wide range of wavelengths. The amount of feedback is controlled by the capacitance of the probe to the cathode line. Even when a circuit is intended to operate only at one frequency it is desirable to provide control of feedback to compensate for variations between valves.

If the circuit dimensions given in fig. 3 are used, the line lengths for several modes of operation and wavelengths are shown by the curves of fig. 8.

The performance curves for the DET24 as an amplifier are shown for two values of driving power (fig. 10). As the driving power is the power actually delivered to the amplifier, the driver stage should provide significantly greater power to allow for losses in the coupling system.

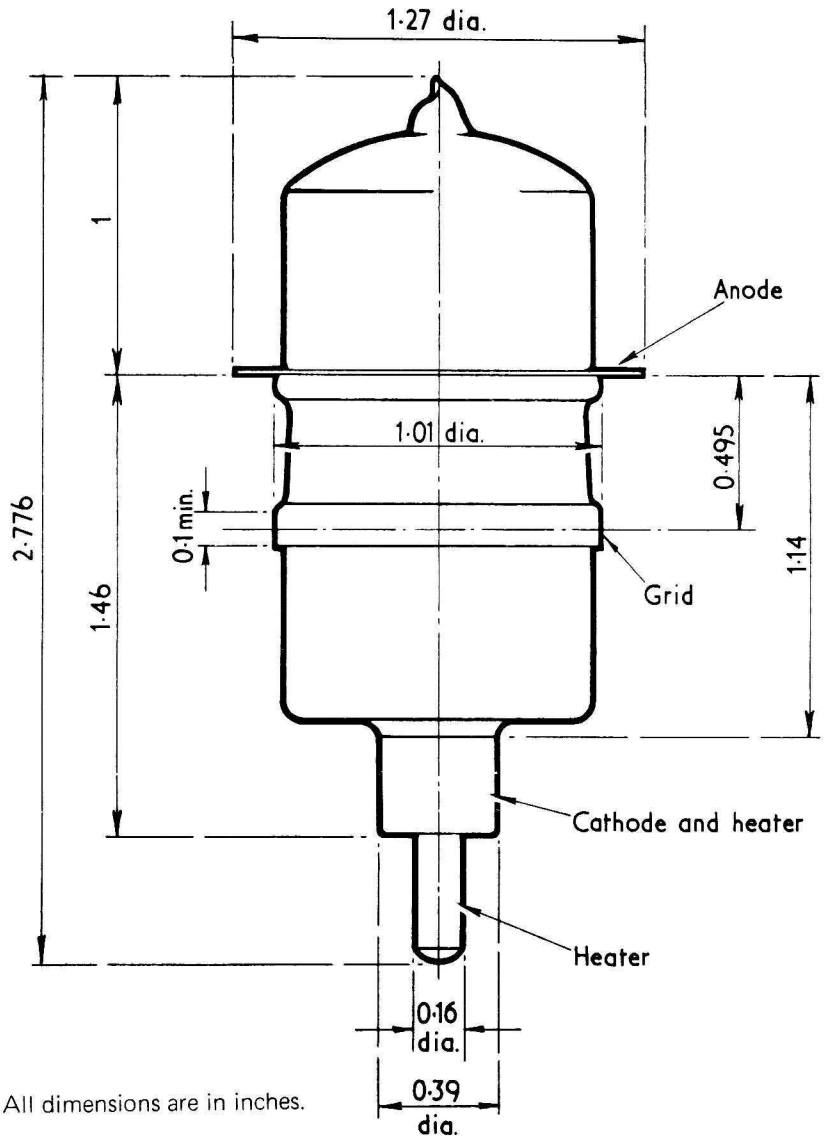
At frequencies below 500 MHz satisfactory performance may be obtained using lumped instead of distributed circuit elements. Application Report No. 10 describes an amplifier designed in this manner.

INSTALLATION

The valve may be mounted in any position but rigid connection must be made to the anode flange only.

The rate of rise of temperature of the metal at the glass-to-metal seals must not exceed 25° C per minute. The maximum temperature must not exceed 140° C.

In order to limit the rate of change of temperature of the anode seal, it is necessary for the mass of metal in close thermal contact with the anode disc to have a thermal capacity of not less than 11 cal/°C. 120 gm of brass or 52 gm of aluminium are suitable.



In order to limit the maximum temperature of the anode seal, the loss of heat from the metal in contact with the seal must be adequate. The seal temperature may be conveniently measured with a temperature sensitive paint.

Provision of circuit information in this publication does not imply a right to use any invention which may be involved and which is the subject of patents by whomsoever owned.

Whilst M-OV has taken care to ensure the accuracy of the information contained herein it accepts no responsibility for the consequences of any use thereof and also reserves the right to change the specification of goods without notice.
M-OV accepts no liability beyond that set out in its standard conditions of sale in respect of infringement of third party patents arising from the use of tubes or other devices in accordance with information contained herein.

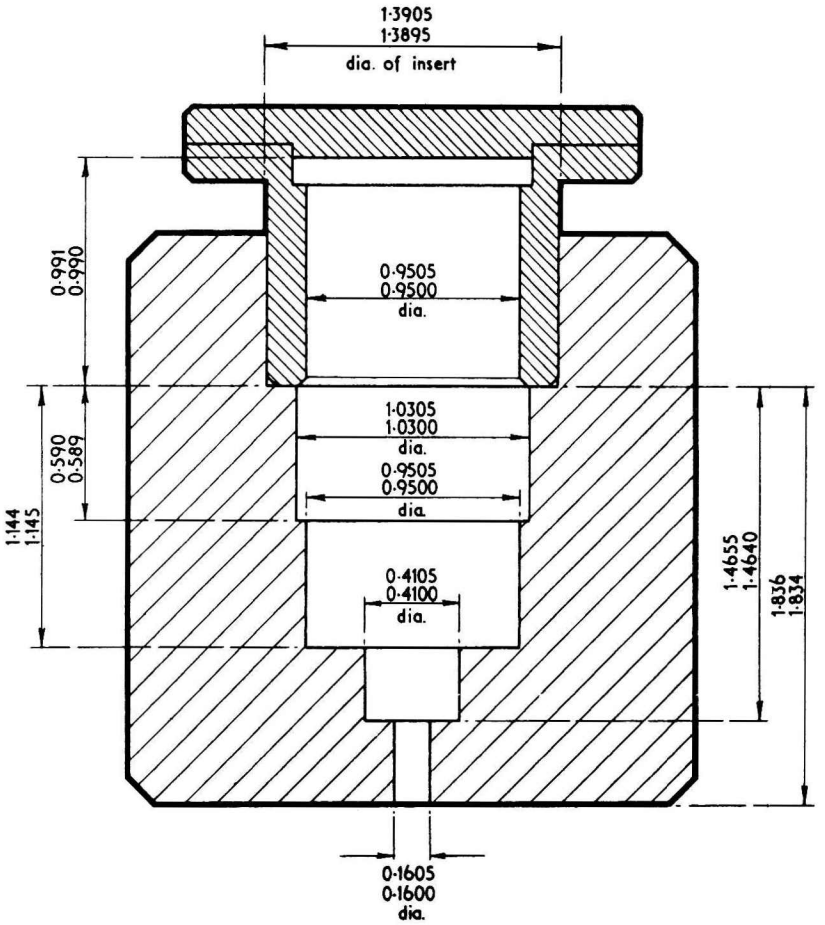


Fig. 1 OUTLINE

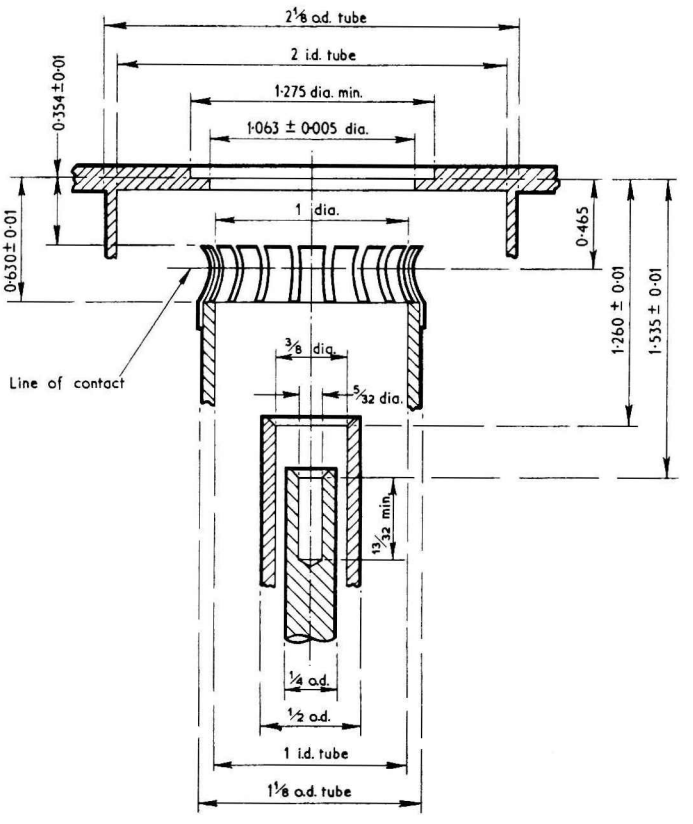
Dimensions are maximum unless otherwise stated. This drawing should not be used for circuit design: see figs. 2 and 3.



All dimensions are in inches.

Fig. 2
To assist in circuit design, this drawing gives the important dimensions of the gauge into which every valve is required to fit before leaving the factory.

All dimensions are in inches.

Fig. 3
Circuit elements made to this drawing were used to obtain the various modes of operation and wavelengths shown graphically in fig. 8.

All dimensions are in inches.

Fig. 4 OSCILLATOR CIRCUIT

The ranges of wavelength obtained with the feedback probe at two different distances from the anode plane are as follows:-

'A'	Range of λ
3.5 cm	25 – 90 cm
7.0 cm	15 – 30 cm

EQUIPMENT DESIGN RANGE

	Max	Min	
V_{a2}	300	160	V/kV_{a3}
$-V_{g1}$	63	28	V/kV_{a1}
D_x	18.2	13.8	$V/cm/kV_{a3}$
D_y	12.2	9.1	$V/cm/kV_{a3}$

TYPICAL OPERATING CONDITIONS (Each Gun)

V_{a1+a3}	1.5	kV
V_{a2}	250 to 450	V
V_g for visual cut-off	−42 to −95	V
*I_{a2} max	150	μA
D_y	15	V/cm
D_x	23	V/cm

*With V_{a2} set for focus, and V_g = −1.0V.

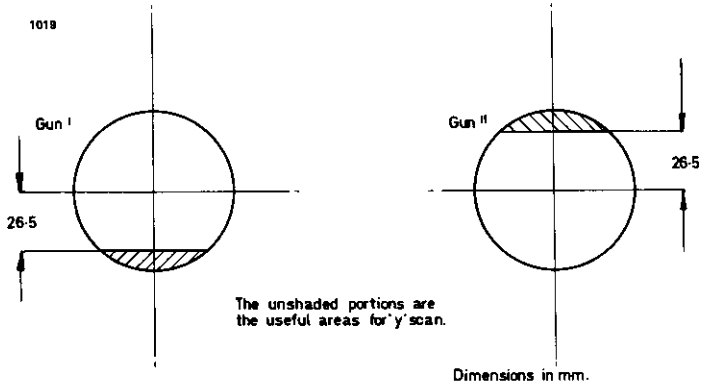
D_y, D_x and V_g for visual cut-off are proportional to V_{a1+a3}.

LINE WIDTH (measured with 24 phosphor)

A value for line width under d.c. conditions is given below.

V_{a1+a3}	1.5	kV
V_{a2}	adjusted for focus	
I_t	1.0	μA
Raster — circle diameter	50	mm
Maximum line width	0.7	mm

EQUALITY OF SENSITIVITIES



Sensitivity variations between the two guns will not differ by more than 5%, calculated as follows:

$$\text{Difference in sensitivities} = 100 - \frac{\text{lower x sensitivity}}{\text{higher x sensitivity}} \times 100$$

MINIMUM SCANNED AREA

x (Full screen)	7.7	cm
y	See Fig. 1	

FIGURE 1

DISPLAY CHARACTERISTICS

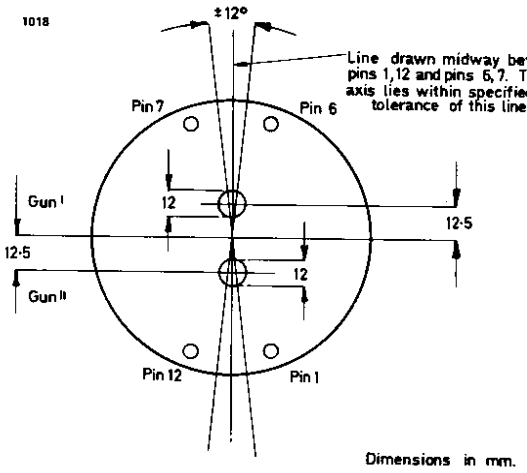
Both x and y plates are intended for symmetrical operation. The tube may be operated asymmetrically, but focus quality will deteriorate and trapezium distortion will be introduced.
The data for raster distortion and line-width will therefore not apply.
In general, the deflection plates should be at the same average potential as a1+a3. However, it may be necessary to adjust the potential of the deflection plates to obtain optimum focus.

Pattern Distortion

Centred at the screen centre, a nominally square raster from either gun may be inserted into the frame bounded by the squares 48.75mm and 51.25mm.

Angle between x and y deflection (each gun)	$90^\circ \pm 1.5^\circ$
Maximum angle between the two x deflections	1.5°
*Maximum angle between the two y deflections	2.5°

*The distance between the two electrical y axes at the geometric screen centre is 3.5mm max.



Pattern Alignment

When two nominally square rasters, whose edges coincide at their centres are superimposed at the screen centre, and when the rasters are simultaneously adjusted in size, the edges will fall within the frame bounded by the squares 48mm and 52mm, giving a total raster misalignment of ±4%.

Spot Position

With the tube magnetically shielded, the undeflected spot of each gun will fall within the appropriate 12mm diameter circle shown in Fig. 2.

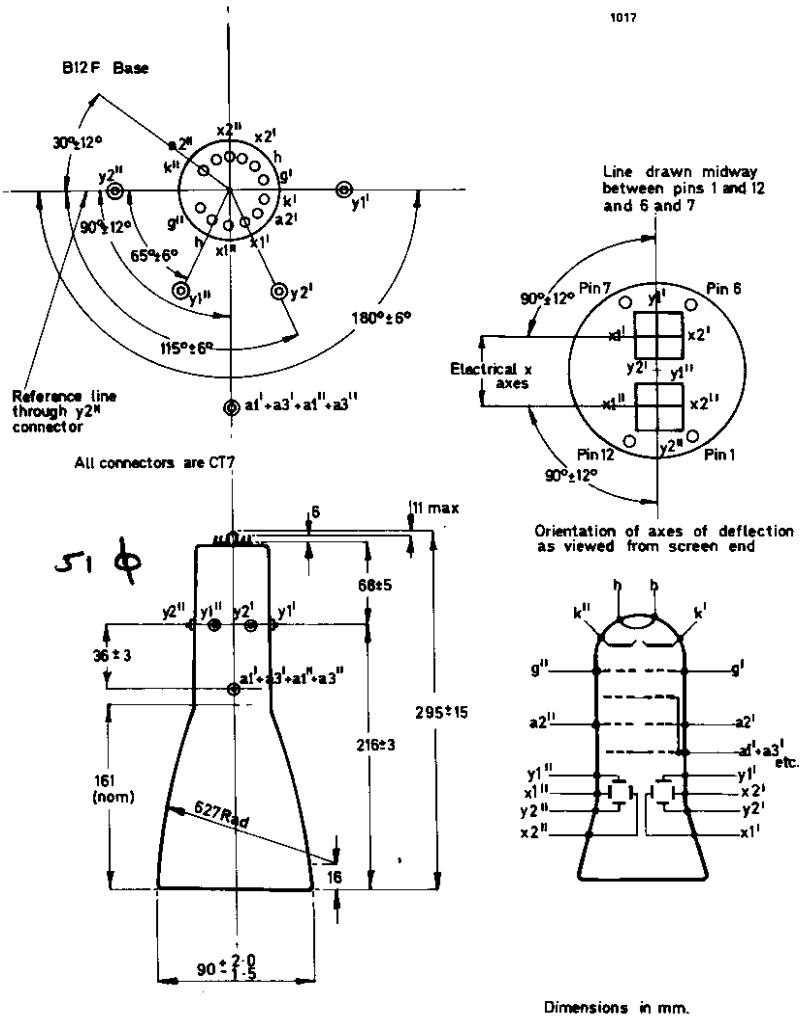
FIGURE 2

MOUNTING POSITION

The tube may be mounted in any position but under no circumstances should the socket be used to support the tube.

WEIGHT

510g.



BASE CONNECTIONS

See drawing.

WARNING

Care should be taken not to expose the tube to strong magnetic fields either in use or during storage.

Dx (max)	12	V/cm
*Typical line width (for type 96 phosphor)	0.44	mm

*Measured by means of a shrinking raster at the geometric centre of the faceplate at 5.0μA beam current.

Minimum Scanned Area

x (each gun)	10	cm
x (overlap)	10	cm
y (each gun)	4	cm
y (overlap)	2	cm

Gun' fills +30 to −10mm and gun'' fills +10 to −30mm about the geometric major axis of the screen.

Beam Blanking

A potential of $-80V/kV_{a1}$ (preferable) or $+100V/kV_{a1}$ with respect to V_{a1} applied to either or both of the blanking electrodes (g2' and g2'') will completely cut-off either or both beams. Blanking electrodes should not be used as brightness controls.

Astigmatism Correction

Adjustment of the potential on a3 relative to the y deflection plate mean potential may be used for the purpose of astigmatism correction. A range of adjustment of $\pm 50V/kV_{a3}$ should be allowed for this purpose.

Pattern Correction

Barrel or pincushion distortion may be minimised by the application of appropriate potentials to the s electrodes relative to the x plate mean potential. Ranges of adjustment (see Typical Operation) should be allowed for this purpose. Astigmatism and pattern correction potentials are quoted for the condition where the x plate mean potential is equal to the y plate mean potential. If, in any application, a difference between x and y plate mean potentials is unavoidable, it is recommended that this difference should be kept to a minimum.

Axis Alignment

The electrical x axis of the tube will lie within ±5° of the major axis of the face plate and may be aligned with this axis by means of the field from an axial coil placed about the cone of the tube.

DISPLAY CHARACTERISTICS

Pattern Distortion

For each beam, with pattern correction applied, the edges of a test raster will lie between two concentric rectangles of 100 x 40 and 94 x 36mm. The angle between x and y axes (each beam) will be 90° ± 1.5° max.
The angle between y axes at screen centre 1.5° max.
The angle between x axes at screen centre 1.5° max.

Deflection Defocusing

The ratio of line width, measured at the centre of a vertical line placed at the centre of the screen, to the corresponding line width measured at edge of the horizontal window will not exceed 2.5:1.

Deflection Linearity

The deflection factor for a deflection of less than 75% of the useful scan will not differ from that for a deflection of 25% by more than 2%.

Spot Position

The focused and undeflected spots will fall within two 15mm squares whose centres lie on the geometric y axis and ±7.5mm from the geometric centre of the faceplate. Gun' spot falls in upper square and gun'' in lower square.

Orientation

Looking at the screen with pins 3 and 4 of the base uppermost a positive potential applied to x1' or x1'' will deflect the appropriate beam to the left and a positive potential applied to y1' or y1'' will deflect the appropriate beam upwards.

MOUNTING

The tube may be mounted in any position but must not be supported by the base alone. It is recommended that the tube should be held by a rubber mask at the screen and a clamp around the magnetic shield near the base, a resilient packing being located between the shield and the tube. The socket should have sufficient freedom of movement to accommodate the maximum overall tube length and base orientation tolerances.

VACUUM SWITCH

DESCRIPTION

The FA-6 is a mechanically actuated, single-pole, double-throw vacuum switch designed to perform switching operations at high speed with low operating pressure and long contact life.

Operation of the FA-6 vacuum switch is unaffected by atmospheric conditions, contacts are free from contamination, and resistance remains low. The construction minimizes arcing at the contacts.

RESISTANCE VACUUM GAGES

DESCRIPTION

The FA-13 and 14, used in a resistance vacuum gage possess features especially useful in providing a convenient method for measuring low gas pressures. With suitable associated apparatus, these tubes will provide a fast, continuous, direct reading. As the vacuum system is pumped down, a meter in the bridge circuit reads the unbalancing of the bridge, thus providing an uninterrupted and instantaneous reading and enabling the observer to determine at all times the exact conditions in the system.

The resistance vacuum gage differs from the McLeod gage in that it gives an electrical, rather than mechanical, indication. Unlike the McLeod gage, it is also possible with this gage to take readings of condensable vapor, such as water vapor.

These tubes should be used in pairs since in combination they provide a much more stable and reliable reading than if the FA-13 is used alone.

TECHNICAL INFORMATION

GENERAL CHARACTERISTICS (Indicator Tube FA-13*)

Number of Electrodes	1

Electrical

Recommended range	0–600 microns
Maximum d-c voltage	6 volts
Resistance of average tube at 25 C	7 ohms

Shipping weight, approx.	3 pounds

OPERATING NOTES

The FA-13 is used to measure the gas pressure. The FA-14, which has a filament identical with that of the FA-13, is sealed off under very high vacuum and is used to compensate for temperature and voltage changes.

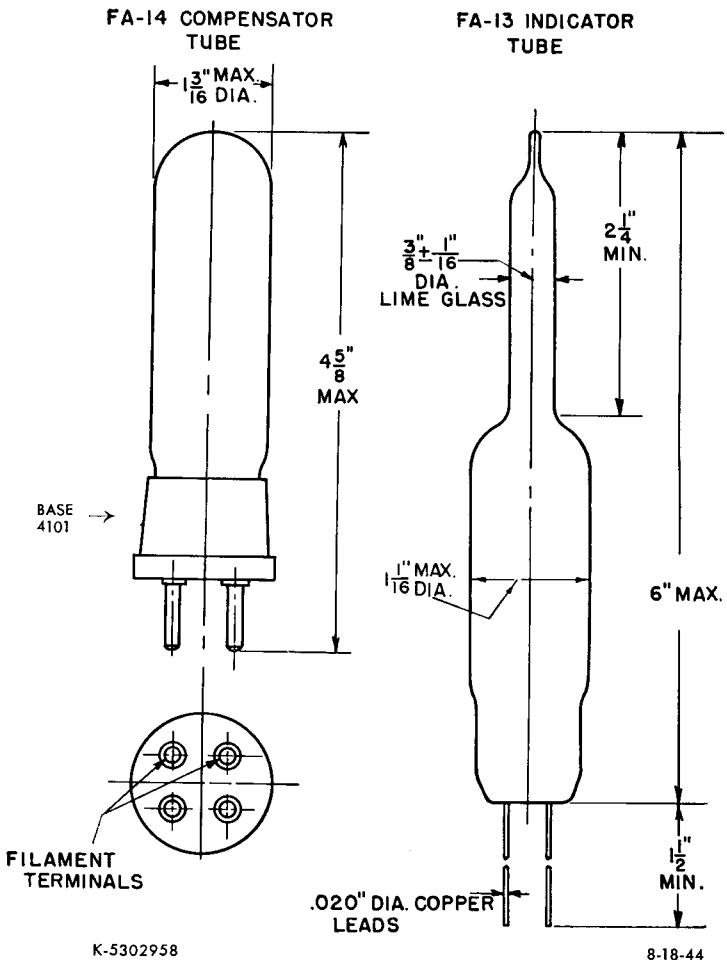
The FA-13 and FA-14 are usually sold in matched pairs since there is some variation from time to time in manufacture. For this reason single tubes purchased separately and at different times may not match.

With the FA-13 the pressure indication is obtained as a function of the change in resistance of a heated tungsten filament caused by the cooling, by convection current, of the gas being measured. Since different gases have different factors for convection cooling, the calibration of the gage will not be the same for all gases. For example, the gage is much more sensitive to hydrogen than to nitrogen. Since the response of the gage is a current change, it may be used for recording and for control—to start and stop a pump—as well as for indication.

INSTALLATION

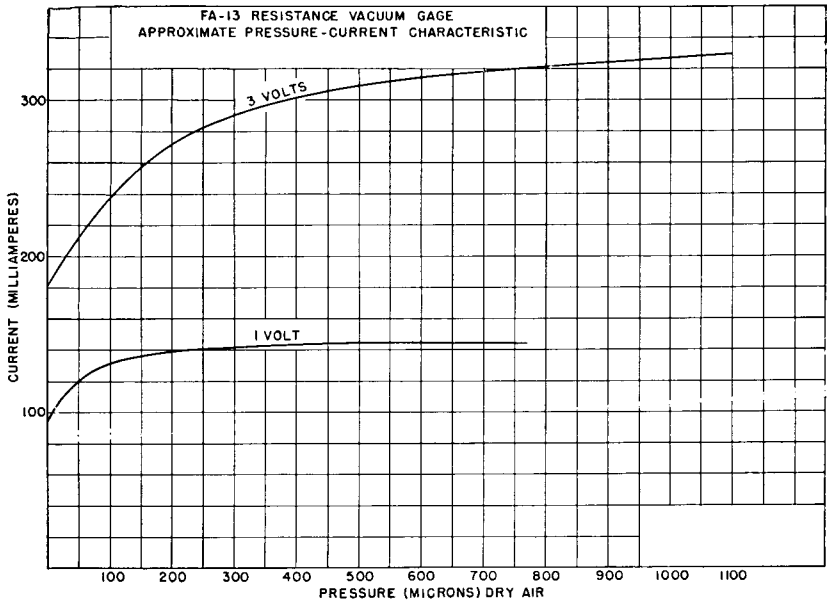
The FA-13 and FA-14 may be mounted in any position, but should be protected from excessive shock or vibration. It is recommended that the connection to the base of the FA-14 be clamped solidly or soldered to avoid difficulty with contact resistance. The FA-13 is provided with connection leads instead of a base and glass connection tubing for splicing to the exhaust system. This connection may be cemented on, or sealed to, another glass tube.

Greater stability will be obtained if tubes are protected from heat and direct light rays. If used in pairs it is advisable to place the tubes together so that their temperatures will vary simultaneously.



OPERATION

Although the FA-13 connected in series with a milliameter, may be used for rough measurements, it is recommended that an ordinary bridge circuit be provided with the FA-13 in one arm, the FA-14 compensator tube in the opposite arm, and variable resistances in the two adjacent arms. The bridge arrangement gives greater sensitivity than the FA-13 alone and the use of a compensator tube results in substantial independence from ordinary voltage variation.



The characteristics shown by the curves are approximate. Where a high degree of accuracy is required, the individual gage must be calibrated against a standard. In Fig. 2, of page 4, the dotted curves are the compensator characteristics plotted in reverse. The distance between the origins represents the total voltage on the bridge; the intersections give the voltage division for various pressures.

With the bridge balanced at zero pressure, the horizontal distances between the zero intersection and the intersection for other pressures furnishes a rough calibration for corresponding measurement taken on the bridge with a high-resistance voltmeter.

These curves supply a convenient method for estimating the bridge sensitivity at various voltages. The calibration may change with wide variations in ambient temperature. Fig. 1 on page 4 illustrates the variation in current with pressure for two different voltages.

VACUUM SWITCH

DESCRIPTION

The FA-15 single-pole double-throw vacuum switch is designed for operation in high-speed relay construction, in d-c circuits involving high inductance, and in installations that require the circuit to be opened by a slow movement.

Since the switch is enclosed in a vacuum, its operation is unaffected by atmospheric conditions, contacts are free from contamination, and resistance remains low. The construction minimizes arcing at the contacts. Only a few thousandths of an inch movement is required to interrupt rated current. This feature coupled with low operating pressure and light weight of the moving parts enables the FA-15 to be operated by a small amount of power.

TECHNICAL INFORMATION

These data are for reference only. For design information refer to specifications.

GENERAL CHARACTERISTICS

Electrical

Interrupting current rating, a-c rms, resistive load current

For total life of 1000 operations at 3000 volts, a-c rms	10 amperes
For total life of 100,000 operations at 3000 volts, a-c rms	3 amperes
For total life of 1,000,000 operations at 3000 volts, a-c rms	1 ampere
For total life of 500,000,000 operations at 3000 volts, a-c rms	0.1 ampere

PHANOTRON

DESCRIPTION

The FG-32 is a half-wave, mercury-vapor rectifier for converting alternating current to direct current. It is adapted to applications where rectification of higher currents at lower frequencies and voltages is desired than is possible with high-vacuum tubes. In comparison with high-vacuum tubes the FG-32 has a relatively low and constant voltage drop which is an advantage in low-voltage rectifier applications as it allows more efficient utilization of power and results in lower circuit losses.

THYRATRON

DESCRIPTION

The FG-81-A is an inert-gas-filled thyratron with a negative control characteristic.

Although inert-gas-filled tubes can be operated in much lower ambient temperatures than mercury-vapor types, they are not rated at as high voltages as mercury tubes of comparable size.

This tube is particularly adapted to applications where it is desired to have current flow in the absence of grid excitation, where constancy of characteristic is required with large variations in ambient temperature and where the tube is subjected to intermittent operation.

The FG-104 is a half-wave, mercury-vapor rectifier for converting alternating current to direct current. It is suitable for applications where rectification of higher currents at lower frequencies and voltages is desired than is possible with high-vacuum tubes. In comparison with high-vacuum tubes, the FG-104 has a low and constant voltage drop which is an advantage in low-voltage rectifier applications since it allows more efficient utilization of power and results in lower circuit losses.

PHANOTRON

DESCRIPTION

The FG-166 half-wave, all-metal mercury-vapor rectifier is capable of carrying peak currents as high as 75 amperes. It is suitable for rectifiers that supply 125 or 250 to 600 volts in capacities of 15 to 50 kilowatts. The sturdy all-metal construction combines mechanical strength with simplicity of design.

TECHNICAL INFORMATION

These data are for reference only. For design information refer to specifications.

THYRATRON

DESCRIPTION

The FG-178-A is an inert-gas-filled thyratron with a negative control characteristic.

Although inert-gas-filled tubes can be operated in much lower ambient temperatures than the mercury-vapor types, they are not rated at as high voltages as mercury tubes of comparable size.

This tube is particularly adapted to applications where it is desired to have current flow in the absence of grid excitation, where constancy of characteristic is required with large variations in ambient temperature, and where the tube is subjected to intermittent operation.

PHANOTRON

DESCRIPTION

The FG-190 is a gas-filled all-metal tube for use as a full-wave rectifier at low voltages. The use of gas imposes a voltage limitation and tubes of this type will not carry as high a voltage as mercury tubes of comparable size. They can, however, be operated in much lower ambient temperatures.

TECHNICAL INFORMATION

These data are for reference only. For design information refer to specifications.

IGNITRON

SPECIAL DESIGN FEATURES

1. Stainless-steel, seam-welded construction
2. Uniform water cooling
3. Strong, compact design
4. Easy to install
5. Copper terminals
6. Flexible anode lead
7. Mercury-pool cathode allows extremely high instantaneous currents to be passed through the tube without damage.

DESCRIPTION

The ability of this tube to carry very high peak currents for short periods makes it especially suited to welder-control service. It may also be used for conversion in low-power circuits and for intermittent rectifier service.

Ease of installation, economical use of space, and reliability of operation are assured by design features inherent in the steel-jacketed construction.

The FG-235-A is similar to the FG-258-A and the FG-271. All of these tubes can be used for a wide range of applications where welds are made infrequently or in rapid succession.

The current range required for the welding operation determines which tube to use. Another factor, of course, is the nature of the material to be welded. Low-resistance materials, such as the aluminum alloys, require more current than such high-resistance metals as stainless steel.

The FG-235-A ignitron is equivalent to a 600-ampere magnetic contactor.

TECHNICAL INFORMATION

These data are for reference only. For design information refer to specifications.

GENERAL CHARACTERISTICS

Peak voltage drop, approx.	12	volts
Net weight, approx.	9	pounds
Shipping weight, approx.	17	pounds
Type of cooling		water
Maximum outlet water temperature	40	centigrade
Minimum flow	1.5	gallons per minute
Minimum inlet water temperature	10	centigrade
Pressure drop per tube at minimum flow	4.1	pounds per square inch
Temperature rise at minimum flow, approx. (Average current 100 amperes per anode)	3	centigrade

MAXIMUM RATINGS

A-C Welder-Control Service—Frequencies From 25 to 60 Cycles—Ratings Are For Any Voltage From 250 to 600 Volts Rms*†

Maximum demand	1200	kva
Corresponding average anode current	75.6	amperes
Maximum average anode current	140	amperes
Corresponding demand	400	kva
Maximum time of averaging anode current*

2. Uniform water cooling
3. Strong, compact design
4. Easy to install
5. Copper terminals
6. Flexible anode lead
7. Mercury-pool cathode allows extremely high instantaneous currents to be passed through the tube without damage.

DESCRIPTION

This steel-jacketed ignitron is designed for rectifier service in the 125-, 250-, 600-, and 900-volt d-c power fields. The FG-238-B is used for rectifiers rated up to 1000 kilowatts depending on the number of ignitrons used, the output voltage, and the circuit.

The FG-238-B is also rated for 2400-volt resistance-welder-control service and has a capacity of 2400 kilovolt-amperes in this service. The FG-238-B has a continuous average current rating of 200 amperes per tube for use in rectifiers rated up to 1000 kilowatts.

Arc losses are low. Phase control of the ignitron impulses permits voltage control of the rectified output. Excitation of the small auxiliary anode stabilizes the cathode spot for very small anode currents. Two ignitors, only one of which is used at a time, assure long life.

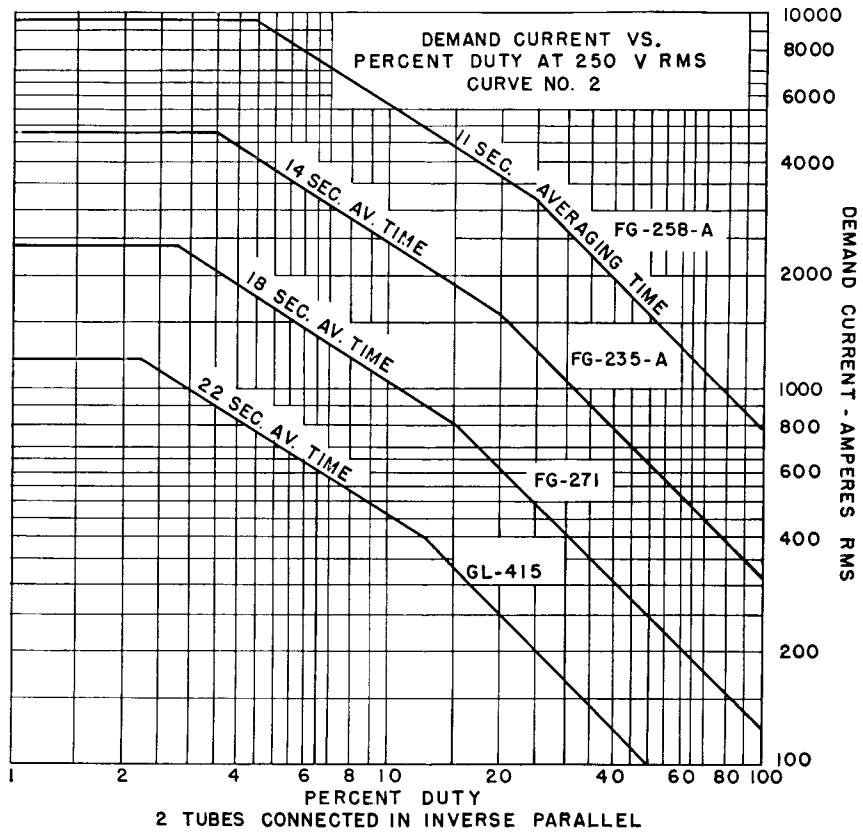
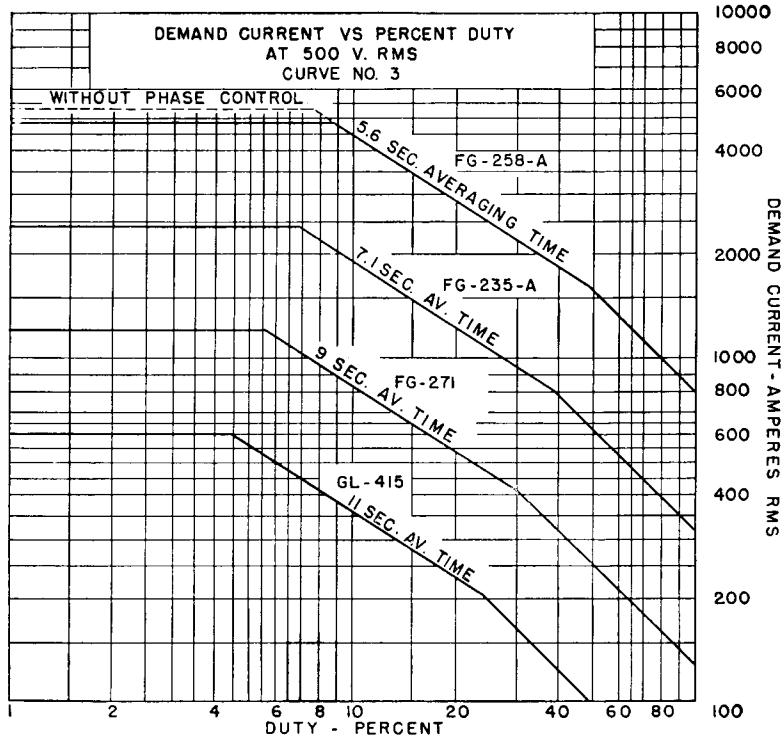
Ignitor ignition time, maximum §	100	microseconds
Ignitor current averaging time	5	seconds

* With the use of log-log paper, straight line interpolation between the two points tabulated may be used to determine other detailed ratings.



† Rms demand voltage, current, and kva are all on the basis of full-cycle conduction (no phase delay) regardless of whether or not phase control is used. For voltages below 250 volts, use the 250-volt rating.

§ Ignition will occur if either maximum required instantaneous positive potential is applied or maximum required instantaneous current flows for the rated maximum ignition time.



Note for Curves of Figures 1, 2, and 3.
In the case of 258-A, a special allowance up to 5300 amperes at voltages below 600 volts is made for panels which fire the ignitor synchronously and with a zero phase delay.

Schenectady, N. Y.

IGNITRON

SPECIAL DESIGN FEATURES

1. Stainless-steel, seam-welded construction
2. Uniform water cooling
3. Strong, compact design
4. Easy to install
5. Copper terminals
6. Flexible anode lead
7. Mercury-pool cathode allows extremely high instantaneous currents to be passed through the tube without damage.

DESCRIPTION

This steel-jacketed ignitron is designed, as is the FG-238-B, for rectifier service in the 125-, 250-, 600-, and 900-volt d-c power fields. The FG-259-B is used for rectifiers rated up to 200 kilowatts depending on the number of ignitrons used, the output voltage, and the circuit.

The FG-259-B is also rated for 2400-volt resistance-welder-control service and has a capacity of 1200 kilovolt-amperes in this service. The FG-259-B has a continuous average current rating of 100 amperes per tube for use in rectifiers rated up to 200 kilowatts.

Arc losses are low. Phase control of the ignitron impulses permits voltage control of the rectified output. Excitation of the small auxiliary anode stabilizes the cathode spot for very small anode currents. Two ignitors, only one of which is used at a time, assure long life.

SPECIAL DESIGN FEATURES

1. Stainless-steel, seam-welded construction
2. Uniform water cooling
3. Strong, compact design
4. Easy to install
5. Copper terminals
6. Flexible anode lead
7. Mercury-pool cathode allows extremely high instantaneous currents to be passed through the tube without damage.

DESCRIPTION

The ability of this tube to carry very high peak currents for short periods makes it especially suited to welder-control service. It may also be used for conversion in low-power circuits and for intermittent rectifier service.

Ease of installation, economical use of space, and reliability of operation are assured by design features inherent in the steel-jacketed construction.

The FG-271 is similar to the FG-235-A and the FG-258-A. All of these tubes can be used for a wide range of applications where welds are made infrequently or in rapid succession.

The current range required for the welding operation determines which tube to use. Another factor, of course, is the nature of the material to be welded. Low-resistance materials, such as aluminum alloys, require more current than such high-resistance metals as stainless steel.

The FG-271 ignitron is equivalent to a 300-ampere magnetic contactor.

PHANOTRON

DESCRIPTION

The FG-280 is a half-wave, all metal, mercury-vapor rectifier for converting alternating current to direct current. It is adapted to applications where rectification of higher currents at lower frequencies and voltages is desired than is possible with high-vacuum tubes. In comparison with high-vacuum tubes, the FG-280 has a low and constant voltage drop which is an advantage in low-voltage rectifier applications as it allows more efficient utilization of power and results in lower circuit losses.

PHOTOTUBE

DESCRIPTION

The FJ-405 is a two-electrode high-vacuum phototube which is highly responsive to ultraviolet radiation between 2000 and 4000 angstroms. This phototube is a precise tool for measurement of ultraviolet radiation in the laboratory. One industrial application is to provide an accurate means of checking the radiation of ultraviolet lamps during manufacture.

PLIOTRON

DESCRIPTION

The FP-54 space-charge-grid tube is designed to have a very high input resistance and a very low grid current. It is designed particularly for amplification of direct currents smaller than about 10^{-9} amperes and has been found capable of measuring currents as small as 5×10^{-18} amperes.

This tube will give the maximum benefits when used to measure very small currents or voltages in very high-resistance circuits. Using a single tube with an input resistor of 10^{10} ohms resistance, the current amplification factor will be 250,000. Since the tube has a voltage amplification factor of less than unity, it should be used in this capacity only as a coupling tube between a high-resistance circuit and another tube which will accomplish the actual amplification. Used in the capacity of an electrometer, with a galvanometer having a sensitivity of 10^{-10} amperes per millimeter connected in the plate circuit, a sensitivity of 250,000 millimeters per volt will be obtained. The FP-54 can be easily installed and operated in a suitable circuit to detect currents as low as 10^{-17} amperes—about sixty electrons per second.

The FP-54 is a convenient and sturdy substitute for a sensitive galvanometer or electrometer in any standard circuit involving the measurement and detection of small currents.

TECHNICAL INFORMATION

These data are for reference only. For design information refer to specifications.

Control-grid plate transconductance	20	micromhos

INSTALLATION

The FP-54 is designed for use with a standard, 0.640-inch pin-circle diameter, four-contact socket. A spring connector should be used for connecting to the top cap. If an attempt is made to solder to the cap, the cement may loosen, causing the lead through the glass to break off. This pliotron may be mounted in any position. The tube must not be subjected to excessive vibration or sudden shock.

For measurements of very small currents, a steady high-resistance unit is required to obtain sufficient voltage drop to operate the tube. A sensitive galvanometer, with an arrangement for balancing out the initial plate current, is required for measurement of plate-current changes.

The surface of the bulb must be kept free from all sources of surface leakage. Remove all traces of foreign matter which might form a conducting path from the control grid to ground.

The air in contact with the bulb must be kept free from moisture. A drier, such as phosphorous pentoxide, placed in the compartment with the tube is satisfactory.

Because of the high leakage resistance of the tube, any change in the total capacitance of the control-grid circuit to ground, such as might be caused by stray capacitive effects, will cause a marked change in the potential of the control grid. Appreciable time will be required for the potential to return to its original value. Since the magnitudes of the plate current deflections measured are quite small, any stray magnetic effects picked up in the associated wiring will cause appreciable deflection. Because of the reasons mentioned above, tube apparatus, including all wiring, meters, controls, and batteries, must be built into a shielded compartment or operated in a shielded room. The tube must also be shielded from air. A metal box will serve both as a shield from air and as an electrostatic shield. If there are large magnetic fields in the vicinity, the shielding must be of iron.

The FP-54 has been designed to minimize all sources of leakage and great care must be taken in its installation not to introduce external sources of leakage. The grid lead and all connections in the grid circuit above ground should be run as directly as possible without any insulators. Should it be necessary to run a lead through the shield, a piece of quartz tubing will make a satisfactory bushing.

Since very small changes in current are measured, the supply voltage must be as nearly constant as possible. Storage batteries of large capacity have proved to be the best source of voltage. Special care must be taken to see that all connections are secure and that controls, such as rheostats and switches, make positive contact and are not subjected to variation by vibration or jar.

OPERATION

Careful handling and conservative operation of this tube will be amply repaid by the longer and more uniform tube life which will be obtained.

During handling, the surface of the bulb will pick up charges, a part of which will leak off through the control grid circuit, appreciably increasing the grid current. Measurements should not be made at any operating conditions without first allowing the tube to run at these conditions for some time. Half an hour will usually suffice for most of these charges to leak off. It may be found advantageous to coat the outside of the bulb with some conductor, such as aquadag, to within an inch or two of the control grid connection. Connecting this con-

ductor to a source of potential equal to that of the grid will facilitate dissipation of the charges on the bulb.

All of the recommended voltages can be varied somewhat without injury to the tube. Operating at higher voltages, however, will tend to increase the grid current. Operating at lower voltages, especially on the filament, will tend to decrease it. It is not advisable to operate with more than 2.5 volts on the filament, more than 6 volts on the space-charge grid, more than 10 volts on the plate, or with less than 3 volts negative on the control grid. When operating with a high-resistance grid leak, if a high input resistance is to be maintained, sufficient grid bias must be applied so that the voltage drop through the grid leak, caused by the grid current, does not cause the actual grid voltage to fall below the recommended minimum value. If sufficient grid bias is not applied the tube will bias itself in the region where the input resistance is low. At the point where the grid current passes through zero in changing from a negative to a positive value, the input resistance is approximately 10^{14} ohms.

In operation, the changes in grid voltage are measured by the changes in plate current. As mentioned above, this may be accomplished with a sensitive galvanometer with the initial plate current balanced out. With this method it is possible to obtain an over-all sensitivity of 250,000 millimeters per volt. Another method is to use an amplifying tube with a high mutual conductance in place of the galvanometer. The plate current of the amplifying tube can then be measured with a less sensitive galvanometer. If the supply voltages are held constant the plate current will remain constant with no tendency to drift.

The following circuits are suggested for use with the FP-54. With slight modifications these circuits may be adapted to any ordinary measurements.

I. Simple one-tube circuit

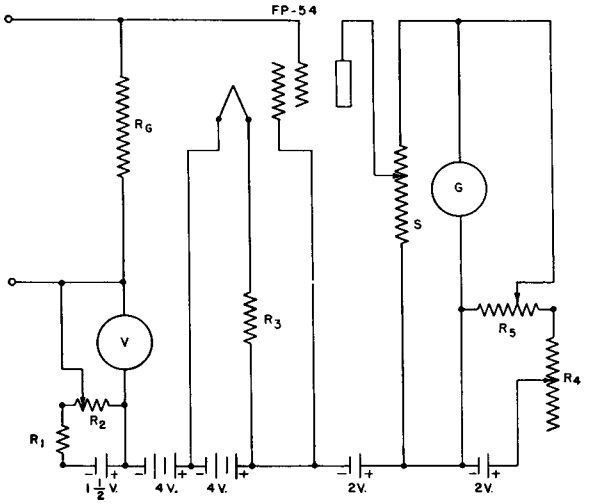
The simple circuit shown in Fig. 1 is recommended for measurements of currents as small as 10^{-14} amperes. It requires only a 12-volt storage battery and a 1.5-volt dry cell.

The method of operation is as follows:

With the filament voltage set at its rated value (2.5 volts) and V reading zero, the galvanometer is made to read zero by adjusting R_1 and R_3. The input current, i, will then produce a change in grid potential, e, equal to $R_g i$ and the change in plate current will cause a deflection of the galvanometer. By adjusting R_2 the galvanometer is brought back to zero. The meter V then reads the value of e, from which i is computed if R_g is known. The sensitivity of the amplifier depends upon the value of R_g and on the sensitivity of the galvanometer. Thus, if g_m is the grid-plate transconductance of the tube

$$g_m = \frac{di_p}{deg} = \frac{I_G}{R_g i} = \frac{kd}{R_g i}$$

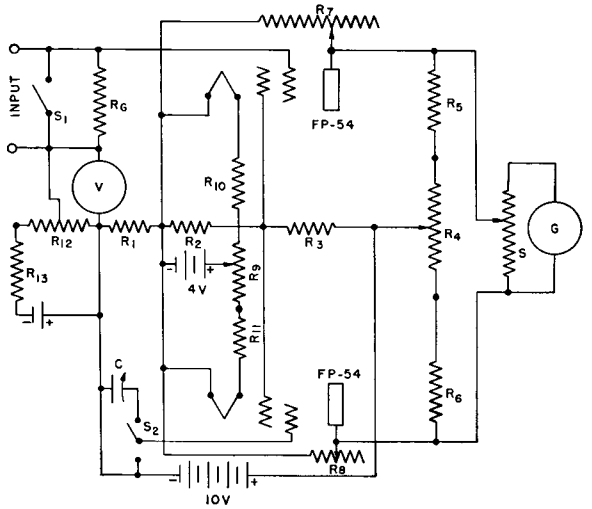
where k is the galvanometer sensitivity, i_G the galvanometer current, and d the galvanometer deflection for the input current i.



For the FP-54, g_m is equal to about 20 micro-amperes per volt. Hence, for example, if $k = 10^{-9}$ ampere per millimeter, $r_g = 10^{10}$ ohms, then d will be 1 millimeter, for $i = 5 \times 10^{-15}$ amperes. The current amplification factor is

$$A = \frac{i_G}{i} = R_g g_m$$

and hence in this example $A = 20 \times 10^4$.



II. Two-tube balanced circuit

For currents smaller than 10^{-14} amperes, the circuit shown in Fig. 2 is recommended. The circuit is balanced by adjusting R_4, R_7, and R_8 so that variations in plate supply voltage will cause no

R_1 = 1000-ohm Resistor
R_2 = 400-ohm Potentiometer
R_3 = 17-ohm Resistor

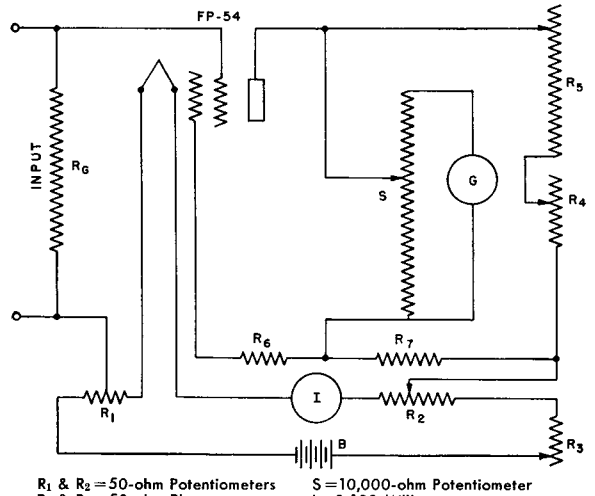
R_{12} = 400-ohm Potentiometer
R_{13} = 1000-ohm Resistor
S = 10,000-ohm Potentiometer
V = 0-200-mv Millivoltmeter

K-8639664 Fig. 2—Two-tube balanced Circuit 8-18-44

change in the galvanometer reading. The effect of R_7 and R_8 is to make the change in current with plate supply voltage in the two circuits equal. An adjustment of R_9 can be found which will make the galvanometer reading independent of filament supply voltage as well. The circuit is then extremely stable and a galvanometer with a sensitivity of 10^{-10} ampere/millimeter may be used, together with a grid resistance of 10^{11} ohms. The ideal sensitivity then will be about 5×10^{-17} amperes per millimeter but, because of the bridge arrangement, the real sensitivity will be half as great, or 10^{-16} ampere/millimeter. The actual amplification factor will be about 10^6.

A still greater sensitivity may be obtained by floating the two control grids—that is, by making R_g infinite and switching S_2 to the condenser C. The potential of each grid will then slowly reduce due to the residual grid current of 10^{-15} amperes. If they reduce at the same rate the galvanometer will still read zero. They may be made to reduce at the same rate by adjustment of the variable 15 micromicrofarad condenser.



The input current i will now cause the potential of the grid of tube *No. 1* to reduce faster, and this will produce a steady drift of the galvanometer, which may be timed with a stop watch. (The circuit is thus simply a vacuum tube electrometer.) The current is then determined from

$$\frac{di_G}{dt} = g_m \frac{de_g}{dt} = g_m \frac{i}{C}$$

where C is the grid capacitance, and is about 6 micromicrofarads for the FP-54. For a galvanometer sensitivity of 10^{-10} amperes per millimeter, a drift of 1 millimeter per second will correspond to an input current of

$$i = \frac{10^{-10} \times 6 \times 10^{-12}}{20 \times 10^{-0}} = 3 \times 10^{-17} \text{ amp}$$

In actual practice such a circuit has been found capable of detecting currents of 5×10^{-18} amperes (about 30 electrons per second).

R_1 & R_2 = 50-ohm Potentiometers
R_3 & R_4 = 50-ohm Rheostats
R_5 = 10,000-ohm Rheostat

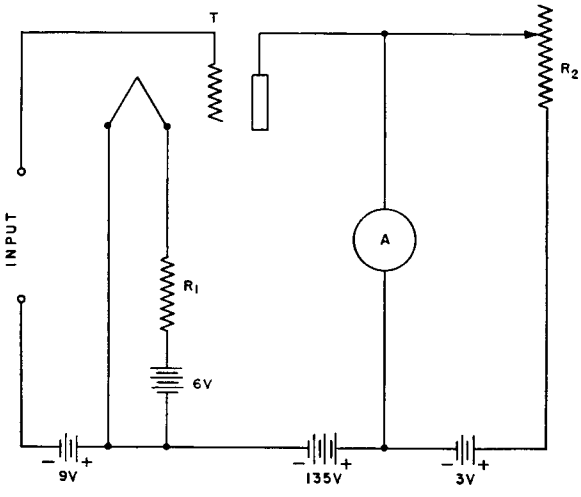
I = 0-100 Milliammeter
G = Sensitive Galvanometer
R_g = 10^7- to 10^{11}-ohm Resistor
B = 12-volt Storage Battery

K-8639662 Fig. 3—Stabilized One-tube Circuit 8-18-44

The galvanometer deflection is calibrated in terms of input voltage using the millivoltmeter V.



III. Stabilized one-tube circuit

In order to obtain the greatest sensitivity using one tube and for making measurements over a long period of time, the circuit shown in *Fig. 3* is recommended.* This circuit can be adjusted so that changes in battery voltage as well as drift in plate current have no effect on the balance of the galvanometer. Adjust the circuit by setting the filament current (I) to obtain approximately the rated filament potential, and bring the galvanometer to zero by varying R_3 and R_4. Then by varying R_2 a point should be found where the rate of change of galvanometer deflection with filament current is zero. If this point cannot be found within a range of plus or minus 3 or 4 per cent of filament current, change the setting of R_2 and repeat. Then balance the galvanometer to zero with R_4 and R_5. After operating for 20 or 30 minutes it may be necessary to readjust R_4 and R_5 for zero balance.

The operation of this circuit is identical with that shown in *Fig. 1* and the same equations for sensitivity and current amplification will apply.

IV. Two-stage amplifier

When it is desired to measure currents of 10^{-9} to 10^{-14} amperes with a very sturdy galvanometer or microammeter, the circuit of *Fig. 4* has been found useful. The first stage may be any of the

R_1 = 4-ohm Resistor
R_2 = 400-ohm Rheostat
A = Microammeter
T = 112-A or Equivalent

K-8639663 Fig. 4—Two-stage Amplifier 8-18-44

circuits previously described but having the input terminals of this second stage connected in place of the galvanometer. The second stage is balanced by adjustment of R_2.

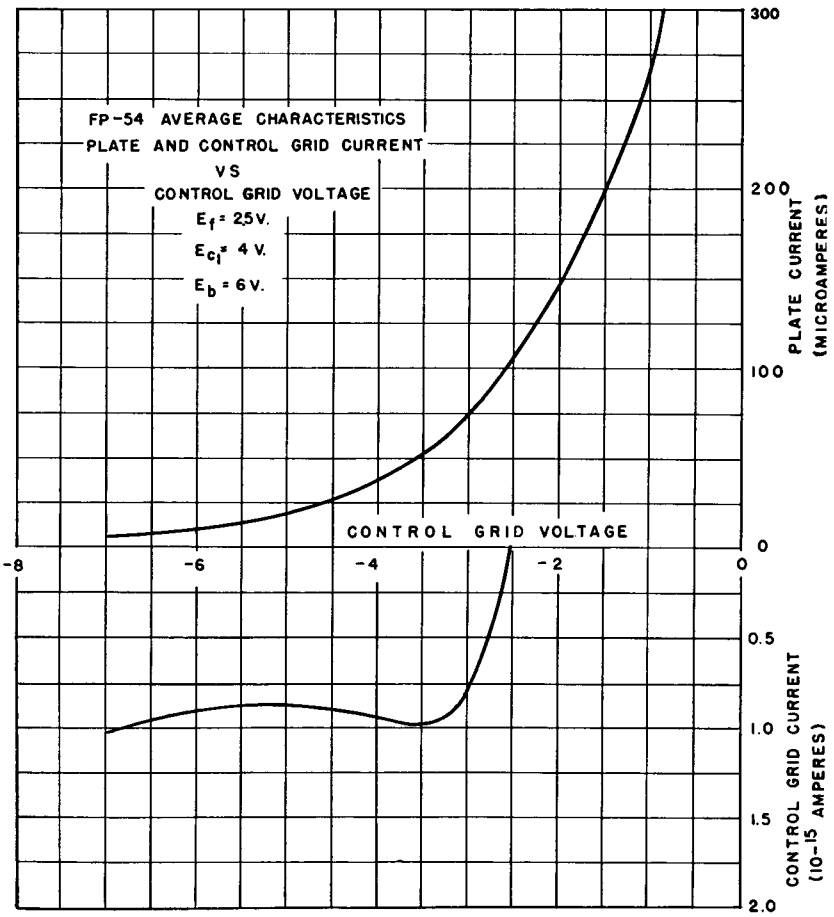
With a microammeter of given range, the sensitivity of the amplifier may be varied by changing the grid resistance R_g. The over-all sensitivity of this circuit connected to the circuit shown in *Fig. 1* or *Fig. 3* is approximately

* *Lee A. DuBridge, and Hart Brown—Review of Scientific Instruments, Vol. IV, No. 10, pages 532–536, October 1933.*

$$\frac{i_A}{i} = \frac{\mu 1\, R_s}{r_p + R_s} \times gm_2 R_g$$

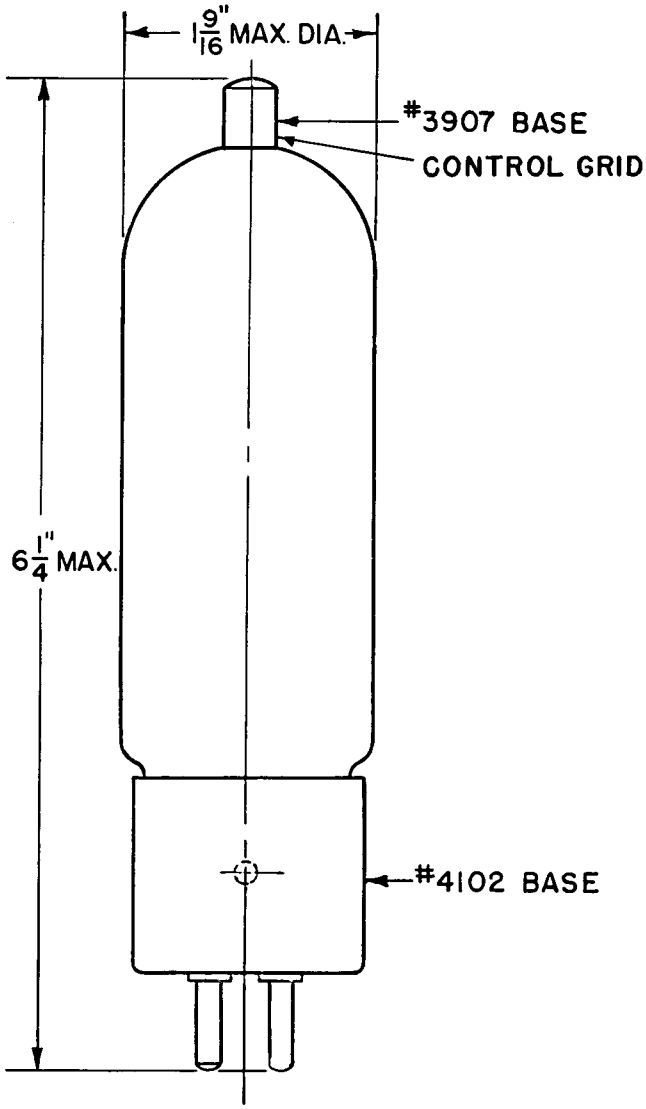
where i_A = *microammeter current*
i = *input current*
r_p = *internal plate resistance of first tube*
$\mu 1$ = *voltage amplification factor of first tube*
gm_2 = *grid-plate transconductance of second tube*
R_s = *resistance of S in Fig. 1 or 3.*

For the FP-54, $\mu 1 = 0.9$ and $r_p = 45{,}000$ ohms, and for the second tube, gm_2 may equal 1500 micromicroamperes per volt. Hence if $r_g = 10^{11}$ ohms and $r_s = 10{,}000$ ohms, an output current i_A of 1 microampere will be obtained for $i = 4 \times 10^{-14}$ ampere (approx) and the current amplification is 2.5×10^7.

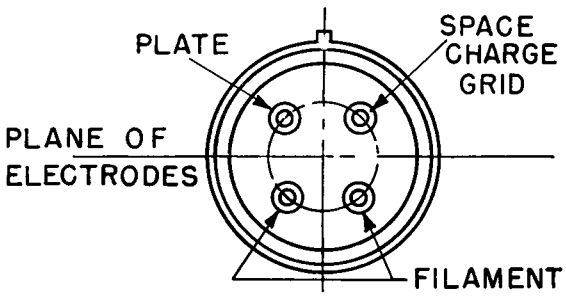


It has been found that i_A is a linear function of i for input voltages ($= R_g i$) less than about 0.5 volt. For larger input voltages, up to 5 volts, a null method should be used to prevent the FP-54 grid voltage becoming low enough to draw a high grid current.

High Resistance



Metallic grid-leak resistors may now be obtained up to 100 megohms and composition resistors up to 10^{14} ohms. Resistances up to a thousand megohms may be made by ruling India ink marks on drawing paper or hard rubber or amber, and inclosing in a drying tube. Still higher resistances may be made by evaporating or sputtering thin metal films onto a glass or quartz rod, keeping the rod in paraffin or in vacuum.



PRECAUTIONARY OPERATING NOTES

1. The whole circuit, including batteries, should be shielded carefully from external electrostatic fields by an earthed metal shield.
2. The tubes should be kept dry. It has been found satisfactory to inclose circuit and tubes in a metal-lined box in which a drying agent is kept.
3. Only the best insulation, such as quartz or amber, should be used in the control-grid circuit. The connections should be self-supporting as much as possible.
4. Rheostat slides should make firm positive contact. Cleaning with sandpaper is advised.
5. The switches S_1 and S_2 used in the circuit of *Fig. 2* should be of small capacitance and without contact potentials.
6. The output current is a linear function of input voltage over only a limited range. The amplifier must be calibrated if a direct deflection rather than a null method is to be used.
7. Keep all batteries in good condition.

PLIOTRON

DESCRIPTION

The FP-62 ionization gage embodies several unique design features which make this tube an efficient and reliable device for the measurement of gas pressures.

Stem leakage is entirely eliminated by mounting the plate, which serves as the positive ion collector, on glass beads and by bringing the plate lead out through the side of the stem. The grid, which serves as the "anode," and the filament, are mounted in the usual manner with the grid between the collector and the filament. The measurement of the small ionization currents associated with low pressures is made possible because of design features which result in high insulation resistance of the collector circuit. Since both the plate and the grid are made of molybdenum and have smooth surfaces, they may be heated to a temperature high enough to drive out all occluded gas within a reasonable time and can readily be heated by bombardment, in case high-frequency heating equipment is not available.

Freedom of the filament from contamination by ordinary gases is assured by its pure tungsten composition. To withstand the effects of flexing in service, the leads to the electrodes are made of a special stranded cable.

For most measurements, where up to twenty per cent error may be tolerated, the sensitivity figures given below may be used. For more accurate measurements, however, the gage should be calibrated with a McLeod gage each time it is installed.

The FP-62 will accurately and conveniently measure gas pressures over a range of 100 microns to as low as 0.001 micron. Not only is it sufficiently sturdy for general use, but it is also sensitive enough for the most delicate measurements.

This gage has a high sensitivity characteristic and, since the parts are rigidly mounted, it will hold its calibration to a very close degree.

TECHNICAL INFORMATION

GENERAL CHARACTERISTICS

Number of electrodes	3	
Electrical		
Filament—pure tungsten		
Normal voltage, approx.	4.5	volts
Normal current, approx.	1.48	amperes
Maximum current	1.68	amperes
Normal operating conditions		
Collector voltage	−22.5	volts
Grid voltage	112.5	volts
Grid current	10	milliamperes
Average sensitivity (collector current per micron of pressure of dry air at normal operating conditions) approx	40	microamperes
Mechanical		
Bulb material		hard glass
Maximum "bake-out" temperature	500	centigrade

TYPICAL CALIBRATION

Grid voltage	112½	volts
Collector or plate voltage	−22½	volts
Grid current	10	milliamperes

Gas	Collector Current in Microamperes per Micron Pressure
Helium	5.6
Neon	9.0
*Nitrogen	39.5
Argon	54.0

* The value given for nitrogen is correct for dry air since the oxygen cleans up when the filament is lighted.

INSTALLATION AND OPERATION

INSTALLATION: The FP-62 is of hard glass and may be used on either hard- or soft-glass systems. When it is sealed to a soft-glass system a graded seal must be used. The gage is furnished exhausted and sealed off and with a tubulation for sealing it into the system. The gage should be kept in this form until it is ready to be used. The end of the tubulation is then cut off and the gage sealed into the system, care being taken that no constriction is formed between the bulb and the system. For accurate results, the gage should be placed as near as possible to the point at which the pressure is to be measured. The gage should be mounted with its axis vertical. The stem may be either up or down, whichever is more convenient. Since, in sealing the gage into the system, the end of the tubulation is cut off and air is let in, it is necessary to exhaust and degas the gage before it can be used. For this reason the gage is furnished unbased to permit its being baked out.

Where high voltages are used in the system and where there is a possibility of a gaseous discharge to the electrodes of the gage, a wire or guard ring should be inserted in the seal when sealing to the system. This wire or guard ring should then be well grounded.

Care should be taken against shorting the leads while anyone is working around the system. The entire collector circuit should be well insulated to prevent the introduction of external sources of leakage. The glass around the collector lead should be clean so that there will be no leakage at that point.

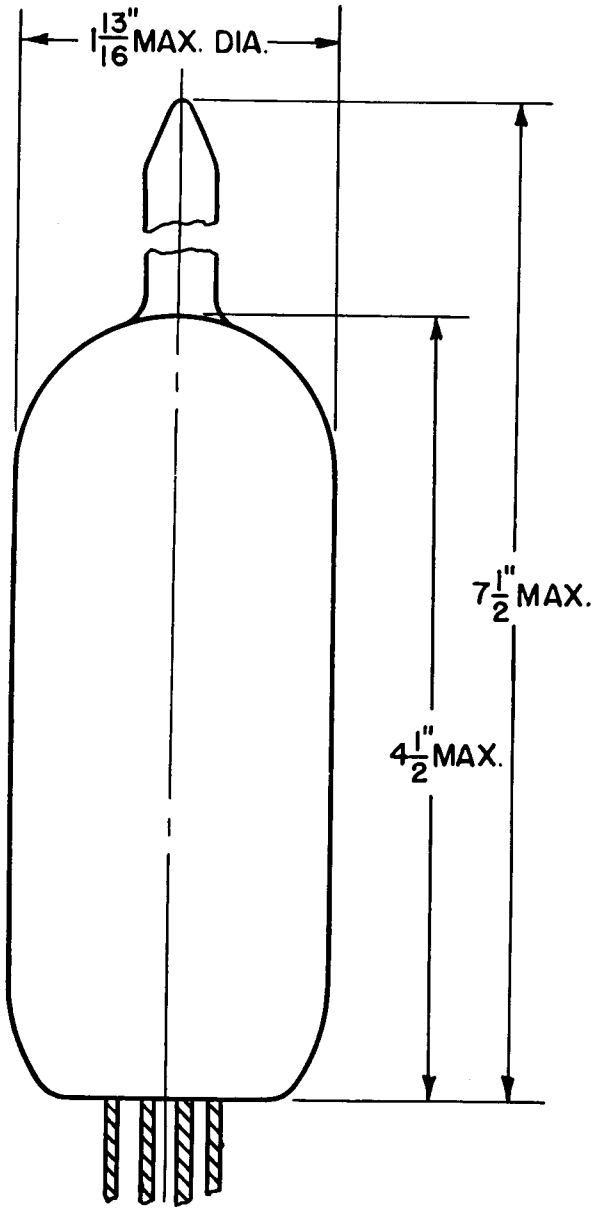
For working at low pressures it is necessary to degas the gage thoroughly. At these low pressures the gas occluded from the metal parts and from the glass may cause the gage to read higher than the actual pressure in the system. Before the gage is used, it should be degassed as follows:

1. Bake out with the rest of the system (do not exceed 500 C).
2. Connect the grid and plate leads to the positive 500-volt d-c supply.
3. Bombard at 1000 C plate temperature for 20 minutes. This is accomplished by regulating the filament voltage to give approximately 40 to 80 milliamperes total current.

Note: Only a d-c voltage supply should be used in this operation.

OPERATION: Measurements are taken with the gage by placing a positive voltage on the grid and a negative voltage on the collector. The filament voltage is increased until the grid current reaches the desired value. The negative current to the collector is then a measure of the gas pressure.

The calibration curve of the gage is nearly a straight line, especially at pressures below one micron. By checking a few points of collector current and gas pressure against a McLeod gage, the curve can be plotted and extrapolated down to



zero current at zero pressure. Typical calibrations for various gases are shown on page 2.

It can reasonably be expected that, as long as the arrangement of the electrodes of the gage remains unchanged, the calibration will also remain constant. Excessive overheating during degassing or rough handling may warp or change the relative positions of the electrodes. Leakage arising in the collector circuit can also cause a change in the calibration. This, however, can be detected by looking for a residual leakage current with the filament cold.

OPERATING NOTES

The filament should not be lighted until the pressure has been reduced to a low value. Care should be taken during bombardment that the gas evolved does not cause the current to increase steadily until the filament burns out or the electrodes are warped. A series resistor will be found satisfactory for avoiding such trouble. As a further precaution, bombardment should not begin until the pressure is below one micron.

In taking readings at extremely low pressures, there are two sources of inaccuracy which may be present. The gage will clean up the gas slowly and give too low a reading. Furthermore, the rate of flow, or rather drift of gas, at low pressure is slow and the gage may read high or low depending on which way the pressure is changing. For best results it is recommended that the filament be turned off and the system allowed to equalize for several minutes. Following this period of equalization the filament should again be lighted and a reading taken as soon as possible.

GENERAL ELECTRIC

General Installation and Operation of Pliotron Tubes

Installation

MECHANICAL

Pliotron mountings must be of good quality and should be so installed as to minimize danger from impact. If the set is subject to vibration, a shock-absorbing suspension must be employed.

COOLING

All apparatus should be arranged to allow free circulation of air around the pliotron. The bulb becomes very hot during operation and, therefore, should neither come in contact with any metallic object nor be subjected to drops or spray of liquid.

Sets using more than one tube should provide adequate spacing between tubes so that adjacent portions of the bulbs do not operate appreciably hotter than the other sections.

ELECTRICAL

To avoid danger of corona discharge, all wires and connections should be made to allow several inches of free space around the pliotron. For tubes using a metal base, the metal shell must not be connected to any part of the circuit.

The filament is of the thoriated-tungsten type, and should be operated preferably from an a-c source, although a d-c supply may be used. A voltmeter should be connected permanently across the filament circuit at the socket terminals so that the filament voltage can be maintained at the ⌀rated value. The filament supply should be designed to allow operation at rated filament voltage. Unless otherwise specified by the manufacturer, any variations which may occur should permit operation of the filament at voltages within the range; namely, rated voltage to five per cent above rated voltage. The filament transformer shall have good regulation and should be designed for at least thirty per cent above rated filament wattage. During "stand-by" periods, the filament voltage should be maintained at rated voltage. If the "stand-by" periods exceed two hours in duration, the filament current should be shut off.

Overheating by severe overload may decrease filament emission. Unless the overload has liberated a large amount of gas, the activity of the filament usually can be restored by operating the filament at rated voltage for ten minutes or more with no voltage on the plate or grid. This process may be accelerated by increasing the filament voltage to 20 per cent above the ⌀normal value (not higher) for a few minutes.

The grid-circuit and plate-circuit return leads should be connected to the center tap of the filament-transformer secondary. When d-c filament excitation is used, the return leads from the grid and plate circuits should be connected to the negative filament terminal.

To prevent parasitic oscillations when pliotrons are operated in parallel, a noninductive resistance of 10 to 100 ohms should be placed in series with each control-grid lead as near as possible to the grid terminal.

An ammeter in the plate circuit of each tube should be connected so that the direct-plate current may be checked regularly.

The plate circuit should be provided with a protective device such as a fuse or relay in order to prevent overheating caused by improper circuit adjustments or overloading. This device should remove the plate voltage instantly if the direct-plate current reaches a value 50 per cent above ⌀normal.

In rating pliotrons, certain values are given as maximum; that is, the values beyond which it is unsafe to go from the viewpoint of life and performance. In order not to exceed the ⌀maximum ratings, changes in plate and filament voltage caused by line-voltage fluctuation, load variation, and manufacturing variation of the associated apparatus must be determined. Then, an average value of plate voltage should be chosen so that under the usual operating conditions the maximum ratings will not be exceeded.

IN TRYING OUT A NEW CIRCUIT OR WHEN ADJUSTMENTS ARE BEING MADE, THE PLATE VOLTAGE SHOULD BE REDUCED IN ORDER TO PREVENT DAMAGE TO THE PLIOTRON OR ASSOCIATED APPARATUS IN CASE THE ADJUSTMENTS ARE INCORRECT.

Operation

GENERAL

Maximum ratings and typical operating conditions for each recommended class of service are given on the Description and

⌀Note: The ratings and characteristics of a particular pliotron are given on the Description and Rating Sheet for that tube.

*Supersedes GEH-980B

Rating Sheet covering the individual type of pliotron. The typical values given must not be considered as ratings, because the tube may be used at any suitable conditions within the maximum ratings.

CLASS A AUDIO-FREQUENCY AMPLIFIER OR MODULATOR

Grid bias for this type of service may be obtained from a separate voltage source or by means of a self-biasing resistor shunted by a filter network to avoid degenerative effects at the low audio-frequencies. When several tubes are operated in parallel, it is necessary to make provision for individual adjustment of grid bias to insure that the plate dissipation of any tube does not exceed the ⌀maximum value. This may be accomplished by means of a tapped "C" battery or, if self bias is used, by means of a variable cathode resistor for each tube. When the self-biasing method is used, separate filament supplies are necessary for each tube.

An output device such as a choke or transformer should be used to transfer power efficiently from the pliotron to the load.

CLASS B AUDIO-FREQUENCY POWER AMPLIFIER OR MODULATOR

In this type of service two tubes are used in a "balanced" circuit, each tube conducting only half the time. The plate loss becomes maximum at a signal slightly less than 1, depending on the circuit conditions, and therefore the plate dissipation must be limited so that at this value of sustained signal, the plate loss will not exceed the ⌀maximum rating.

The input transformer should be designed to give good frequency response when operated into an open circuit, such as that represented by the grid circuit of the Class B stage when the signal amplitude is small. It should be designed also to handle the required input power for maximum signal conditions.

The output transformer should be designed so that the resistance presented by the load is reflected as the proper plate-to-plate loading in the Class B stage. For example, if the load is a modulated Class C amplifier operating at 2000 volts and 500 milliamperes, the ratio of the output transformer to provide a plate-to-plate loading of 10,000 ohms would be $\sqrt{10000 \div 4000}$, or 1.58 to 1, step-down. The transformer should be designed with a core large enough to avoid saturation effects, which would impair the quality of the output. If the secondary is to carry the direct plate current of the modulated amplifier, the core should be made larger and should include an air gap.

CLASS B RADIO-FREQUENCY AMPLIFIER

In Class B radio-frequency service, the plate is supplied with unmodulated direct voltage, and the grid is excited by modulated r-f. voltage. It is important to note that in this service the plate dissipation is greatest when the carrier is unmodulated. Therefore, the circuit should be adjusted so that, without modulation, the plate loss will not exceed the ⌀maximum rating.

Grid bias for Class B a-f. or r-f. service should be obtained from a battery or other d-c source of good regulation. It should not be obtained from a high-resistance supply such as a grid leak.

CLASS C RADIO-FREQUENCY POWER AMPLIFIER -- PLATE MODULATED

In this type of service, the plate supply voltage is modulated so that the tube output is modulated radio frequency. Assuming a value, P, of plate input to be modulated, the amount of audio-frequency power to be supplied is equal to $\frac{m^2P}{2}$, where m is the modulation factor.

The maximum ratings and typical operating conditions given in the ⌀Technical Information are such that a modulation factor up to 1.0 may be used. When a lower value of modulation is used, the plate dissipation allowed may be increased, but should be limited so that with the modulation sustained at its peak value, m, the plate loss will not exceed a value $\frac{3}{2+m^2}$ times the plate dissipation rating.

Grid bias for this service may be obtained from a grid leak or from a combination of grid leak and generator, rectifier, or cathode-bias resistor, suitably by-passed for audio- and radio-frequencies. The combination method is desirable because distortion effects may be minimized.

CLASS C RADIO-FREQUENCY POWER AMPLIFIER AND OSCILLATOR

In telegraph service, the plate input power is keyed, i.e., is on and off alternately in accordance with the characters of some code. During the "key-down" periods, the tube functions as an unmodulated radio-frequency power amplifier. The tube may be used also as an amplifier or oscillator without keying. In both types of service, the ratings given are for "key-down" conditions.

Certain methods of modulation may be applied to this class of service provided

⌀Note: The ratings and characteristics of a particular pliotron are given on the Description and Rating Sheet for that tube.

the modulation is essentially negative, and the positive peak of the audio-frequency envelope does not exceed 115 per cent of the carrier conditions.

Grid bias for Class C service may be obtained from a grid leak, from a battery, from a rectifier of good regulation, or from a self-biasing resistor by-passed with a suitable capacitor. With the grid-leak method, the grid excitation must not be removed without also removing the plate voltage. Grid-bias values are not particularly critical, and correct circuit adjustment may be obtained with widely different values.

INSTRUCTIONS

Complete instructions are packed with each shipment of tubes. Additional copies can be secured from the nearest office of the General Electric Company.

General Electric tubes are warranted to be of the kind and quality described in the manufacturer's specifications. Before leaving the factory, each tube is subjected to rigid tests and inspections. Performance will depend, to a large extent, upon the application, and upon the care with which the tubes are handled. In case of doubt as to proper operating conditions, information should be secured from the General Electric Office through which the purchase was made.

To assure satisfactory operation, it is recommended that each tube be tested upon receipt by the customer, in the equipment in which it is to be used. If spare tubes are to be stocked for long periods, a check test should be made every three months. The conditions of test and operation should not be more severe than the conditions described in the specifications.

If any failure of the tubes to comply with the specifications appears during the initial test or subsequently during the life warranty under which the tubes were purchased, the General Electric Office through which the purchase was made will advise the purchaser regarding the correct procedure for returning tubes believed to be defective.

Should the package be received in damaged condition, observance of the procedure described on the tag affixed to the container will enable the General Electric Company to assist the customer in filing a claim for tubes damaged in transit.

Tubes returned for credit adjustment should be packed as carefully as when originally received, for damage sustained in return shipment will make a thorough examination impossible.

LICENSE NOTICE

In connection with this device, the General Electric Company has rights under patents having claims (a) on the device itself and (b) on combinations of the device with other devices or elements, as for example in various circuits and hook-ups.

The sale does not carry a license under the patent claims of (b) except for installation and legitimate renewals and repairs in apparatus and systems already licensed for use under such patent claims on combinations.

Service Report Form

This service sheet is furnished for the convenience of the customer in applying for adjustment if the quality of the tube does not meet the specification and warranty under which the tube was sold. It is essential that the customer, in making application for adjustment, fill out this sheet and return it, with the tube, to the commercial agency from which the tube was purchased.

In returning a vacuum tube for test and examination, the customer gives permission to the General Electric Company to break the glass bulb and to dissect the structure of the tube, in case such procedure is considered necessary for a complete examination of the tube, to determine whether or not the failure was caused by a manufacturing defect.

PLIOTRON

DESCRIPTION

The FP-265 is a high-vacuum tube designed for use as an oscillator and radio-frequency amplifier in high-frequency circuits.

The plate lead is brought out the top of the bulb, and the grid lead is brought out through the side wall of the stem tube to the cathode base. The mount is supported by a special insulator so that the clamp and supports are not connected to the plate.

The filament of the FP-265 is designed to provide ample emission for operation in circuits utilizing half-wave alternating current. In designing the filament transformer, conditions should be chosen so that the filament voltage is never less than 10 volts nor more than 10.5 volts for continuous operation. For less than one hour of operation, a filament voltage up to 11 volts is permissible.

TECHNICAL INFORMATION

These data are for reference only. For design information refer to specifications.

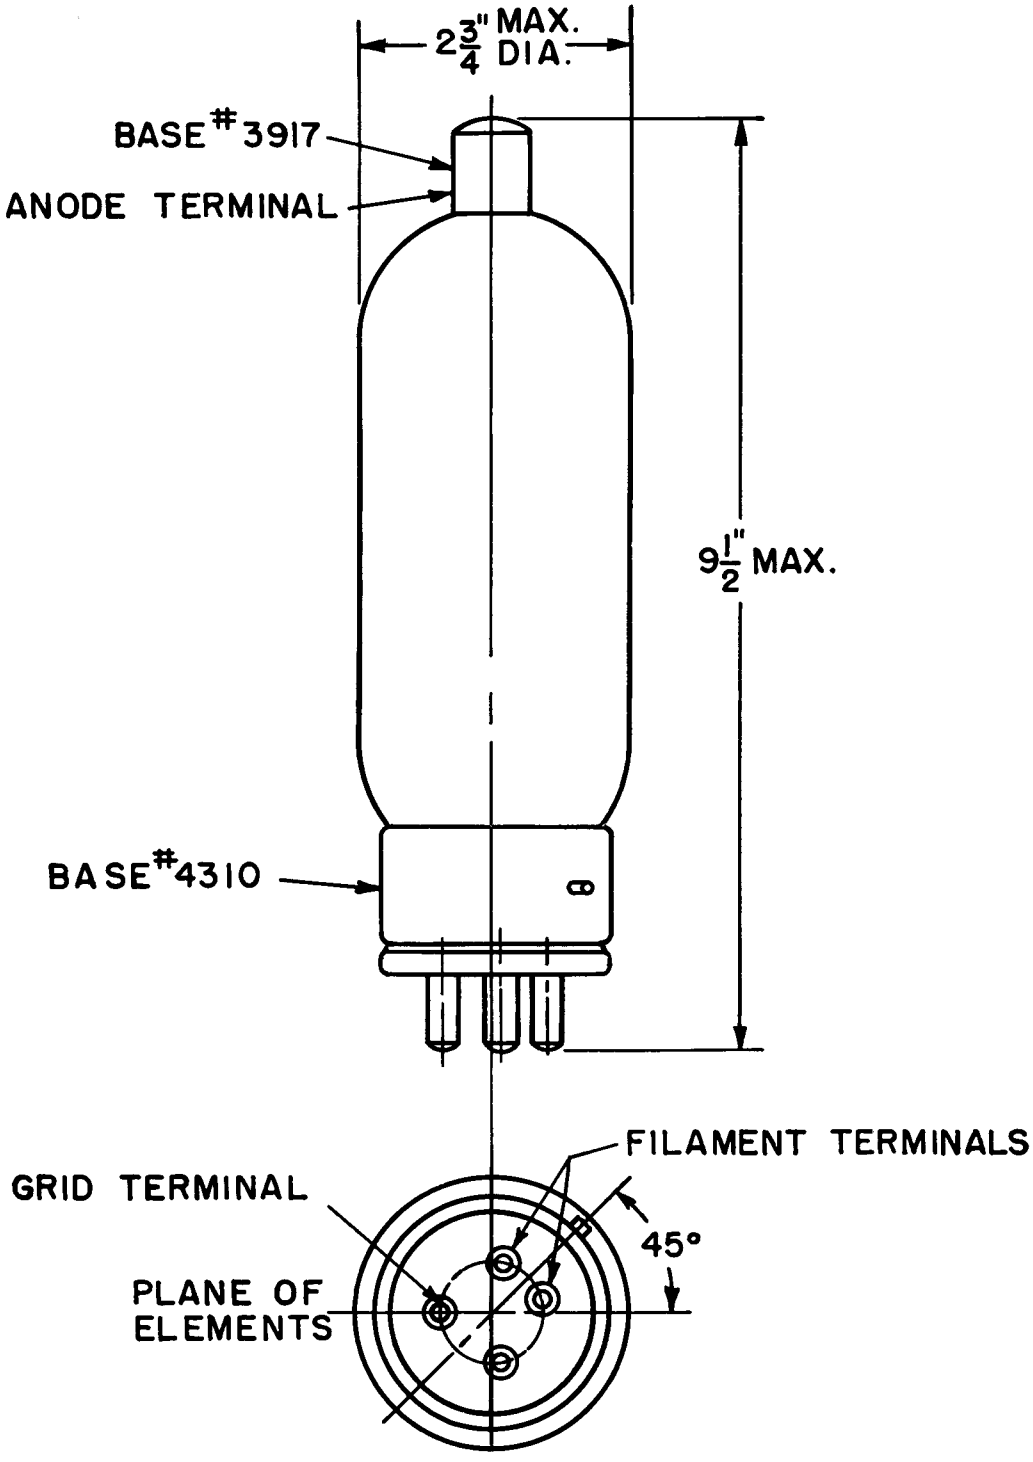
R-f grid current	....	10	amperes
Plate input	....	350	watts
Plate dissipation	130	160	watts
Plate power output	200	....	watts



APPLICATION NOTES

The normal value of grid leak, when the tube is used as an oscillator or r-f power amplifier (Class c), is in the neighborhood of 3000 ohms, although this may be replaced by a suitable fixed bias. If self-bias is used, the cathode resistor should be approximately 500 ohms. In some cases, to minimize the danger of overloads, a combination of grid leak and partial self-bais may be desirable. The values should be chosen so that the plate loss at the worst condition is limited to the maximum rating.

The maximum ratings apply only at frequencies below 15 megacycles. For operation at higher frequencies adequate ventilation and normal ambient temperatures must be maintained, and the plate voltage must be reduced as indicated.

Frequency	15	30	40	megacycles
Percentage of maximum rated Plate voltage and plate input	100	75	50	per cent

With the grid connected to the plate through the shortest possible connection, the resonant frequency of the grid-plate circuit is approximately 100 megacycles.

PLIOTRON

DESCRIPTION

The FP-285 is a high-vacuum tube suitable for use as an oscillator and radio-frequency amplifier in high-frequency circuits.

This tube is especially satisfactory when used to generate the ultra-high frequencies required in short-wave therapy equipment. The hazard of stem puncture, a common fault in some tubes used in such applications, has been eliminated by bringing the plate and grid leads out through the side wall of the cathode stem. Low plate-to-filament capacitance and good insulation, especially important features in tubes for high-frequency service, are assured by the use of a special insulator which supports the mount and holds the clamp and supports away from the plate.

These, together with the other design features inherent in pliotrons of this type, result in economical, dependable operation and long life.

KENOTRON

DESCRIPTION

The FP-400 is a diode designed to be used in the study of electrical discharges in high vacuum. It contains a pure-tungsten filament, located axially in a cylindrical zirconium-coated-nickel anode. It is particularly well adapted to the following studies of fundamental electronic phenomena:

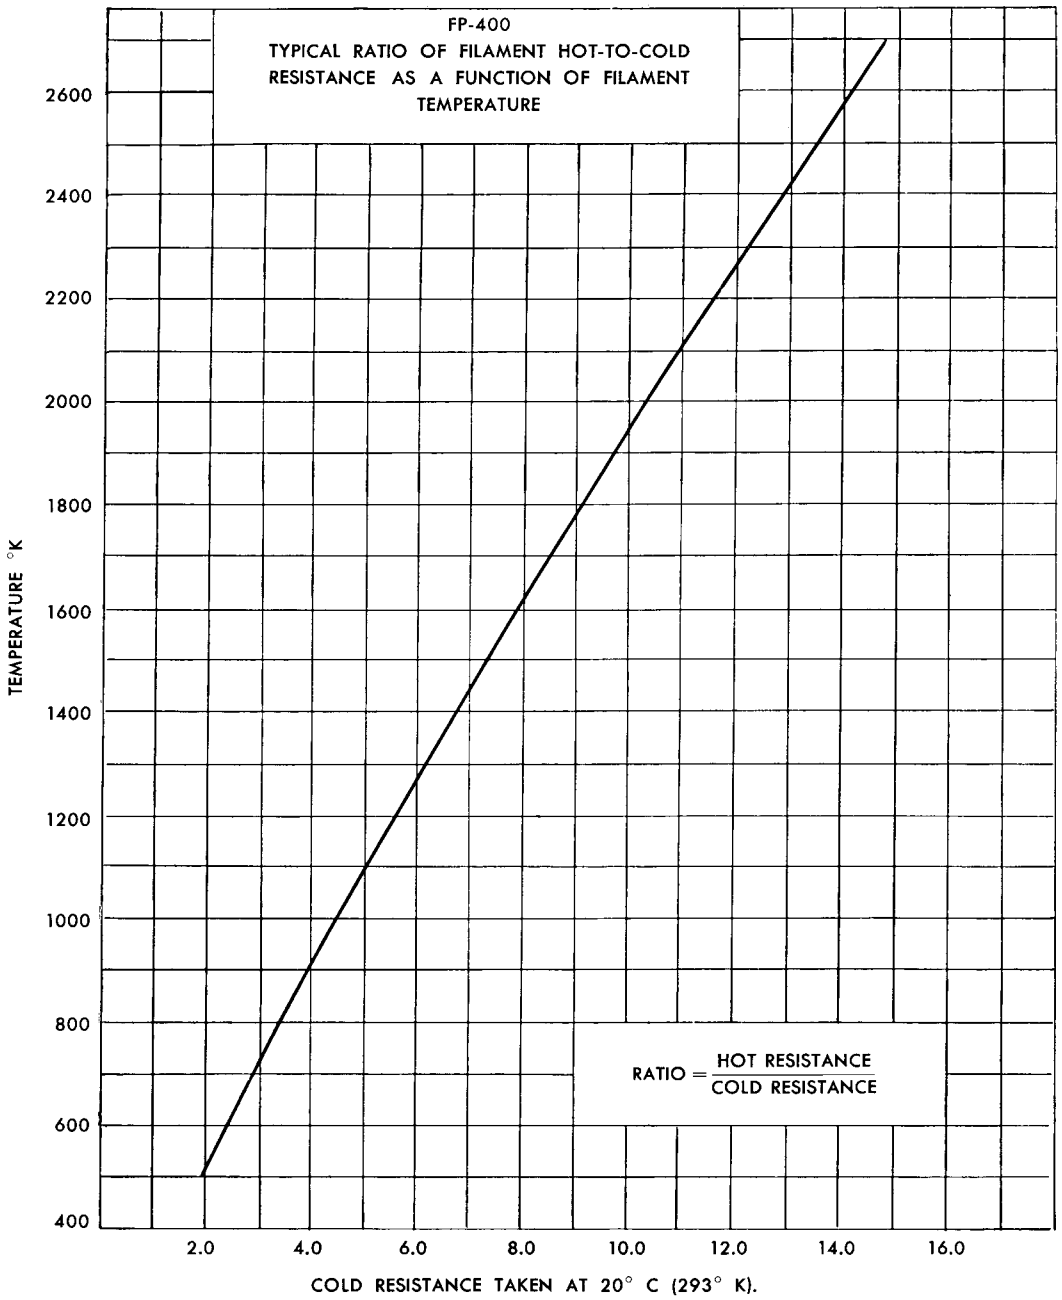
1. The limitation of current by space charge
2. The relation between temperature and electron emission
3. The effect of magnetic fields on electron currents

The pure tungsten filament used renders this tube especially advantageous for emission studies.

TECHNICAL INFORMATION

These data are for reference only. For design information refer to specifications.

GENERAL CHARACTERISTICS



Number of electrodes	2	
Electrical		
Filament—Pure tungsten		
Voltage	4.0	volts
Current	2.25	amperes
Average filament lead resistance, excluding filament	0.08	ohm
Mechanical		
Maximum over-all dimensions		
Length (free length of filament)	1.25	inches
Diameter	0.005	inch
Anode, zirconium-coated-nickel, inside diameter	0.620	inch
Base		Medium 4-prong bayonet
Mounting position		Vertical or horizontal

GE Electronic TUBE

TECHNICAL INFORMATION (CONT'D)

MAXIMUM RATINGS

	Typical Operation	Maximum Ratings
Filament voltage	4.0	4.75 volts
Filament current	2.25	— amperes
Anode voltage	100	125 volts
Anode current	0.025	— amperes
Anode dissipation	—	15 watts
Magnetron characteristics		
Magnetic field for anode voltage = 80 volts		
At normal anode current	Below 80 gauss	
At minimum anode current	Above 130 gauss

INSTALLATION

Mechanical

Mountings should minimize danger from vibration and impact. Special attention should be given the socket to assure firm, low-resistance contact with the filament terminals of the base.

Cooling

All apparatus should be arranged to allow free circulation of air around the bulb which becomes very hot during operation and, therefore, should neither come in contact with any metallic object nor be subjected to drops or spray of liquid.

Electrical

The filament may be operated from either an a-c or a d-c source. For accurate measurements of filament voltage and current, a d-c source is preferable. The voltage rating of the filament makes the use of a six-volt battery convenient.

The anode-circuit return lead should be connected to the negative filament terminal when d-c filament supply is used. The negative filament terminal of the base (see outline) is connected in the tube through the lowest possible lead resistance to the end of the filament.

OPERATION

Maximum ratings and typical operating conditions are given above. It should be recognized that the life of a tungsten filament decreases with increased temperature, and that at temperatures above about 2600 K, the length of life of tungsten filaments under tension is difficult to predict due to the possibility of rupture caused by accelerated crystallization.

The theoretical space-charge equation for concentric cylinders is,

$$I = 14.65 \times 10^{-\frac{6V^{3/2}}{rB^2}}$$ amperes per centimeter length of filament

Where V = anode voltage and
r = anode radius (centimeters)

B^2 is a function of the ratio of the anode radius to cathode radius. The derivation of this equation, and values of B^2 may be found in the references (1) and (2).

The space-charge equation may be applied without major discrepancies to practical cases, particularly where the variation of current with voltage is desired. Where an actual filament is used as the emitter, and it is desired to obtain the anode current for a given anode voltage, some correction must be made to allow for the fact that the filament is cool at each end. For the FP-400, satisfactory results are obtained by basing the calculations on a filament length of one inch. A more accurate correction for each filament temperature may be obtained by using the theory of end losses (3).

For a study of space-charge, curves similar to those shown may be plotted from data taken in the laboratory. (For use in the study of emission, it is convenient to measure the saturated emission currents at different filament voltage levels while obtaining these data. At each filament voltage level, the filament current should be measured accurately.)

These curves may be checked as to slope (the exponent in the space-charge equation) by plotting slightly to one side a straight line representing the equation, $I = KE\ 3/2$ where K is arbitrarily chosen to make the line fall near the curves.

The several causes for the deviation of the curves from a straight line before saturation occurs form an interesting field for qualitative studies.

The Relation between Temperature and Electron Emission

The data necessary for this study may be obtained while making measurements of the space-charge limited currents, as described above.

Dushman's equation (4) for thermionic emission is,

$$I = AT^2\ E^{-\frac{b_o}{T}}$$ amperes per square centimeter

Where T = absolute temperature of the emitter
$A = 60.2$
$b_o = 52{,}400$ for pure tungsten

Observed values of the properties of tungsten have been recorded by H. A. Jones and I. Langmuir (5).

The saturated emission currents measured may be checked against the corresponding filament temperature, using the Dushman equation or the observed properties of tungsten. Actual filaments, however, always vary in temperature from the center to each end, due to the cooling effect of the leads. A temperature may be found by means of the hot-to-cold resistance ratio.

The cold resistance is measured at room temperature. If the room temperature is appreciably different from 20 C, a correction on the measured value may be used. This measurement will include the filament resistance, and the resistance of the filament leads. The resistance of the filament alone may be found from the known length and diameter of the filament and the properties of tungsten (5). In this way, the resistance of the leads may be found.

The hot resistance of the filament circuit is found by measurements of voltage and current. The usual precautions regarding voltmeter current should be observed when making such measurements. The hot resistance may then be corrected for the resistance of the leads, and the ratio of hot-to-cold resistance found.

The temperature determined in this way will obviously be an average value, less than the center

See Footnotes 1, 2, 3, 4, 5 and 6 on page 6.

temperature of the filament, and greater than the temperatures.

It will also be subject to major errors because of the errors of measurement in finding the cold resistance. The emission determined by use of this temperature will usually be far below that measured, because of the exponential increase of emission with temperature.

The temperature at the center of the filament may be discovered with a high degree of accuracy by determining the function, A' (amp/(cm)3/2) and arriving at the corresponding temperature (5). Then, the emission to be expected from the entire length of filament running at this maximum temperature may be corrected by means of the factor obtained from the theory of end losses; (3), (5):

$$f = \frac{V + 2\triangle V}{V + 2\triangle V - 2\triangle V_H}$$

Where V is the filament voltage

$\triangle V$ is a function of the maximum temperature and the filament-to-lead-junction temperature

$\triangle V_H$ is a function of the exponent (with respect to temperature) at which the property (emission) increases, and the temperature

The lead-junction temperature of the FP-400 filament may be considered one-quarter the maximum temperature. The leads connected to the filament are molybdenum, 0.030 inch in diameter. Another method of arriving at a temperature, in this case too low, is to measure the input to the filament, in watts, and use the function W' (watts/length $\times$ diameter) to find the temperature (5). On the chart, "Specific Characteristics of Ideal Tungsten Filaments" (5), the function I' (amperes/length $\times$ diameter) may be found directly, if desired.

When the Dushman equation is used to check the variation of emission with temperature against the measured values, it will be found that the value of A given in the emission equation will not apply to the experimnetal results; the discrepancy depends on whether an average temperature or the maximum temperature of the filament has been found. If the maximum temperature has been found, the factor, f (a function of temperature), mentioned above may be used to correct the value of A in the Dushman equation for the effect of end losses (5). If the value of A in the Dushman equation is corrected for one of the points taken, so that the calculated emission agrees with that actually obtained, the other points will agree quite well with the equation.

The Effect of Magnetic Fields on Electron Currents

The FP-400 is designed to demonstrate the influence of a magnetic field on a moving stream of electrons. The theoretical and actual performances of magnetrons are discussed in the references (1), (6).

The tube may be surrounded by an air-cooled field coil which will produce flux parallel with the filament. The flux produced by this coil should be measured. Data may then be taken for curves showing the cut-off characteristics of the tube. The critical value or cut-off value of flux is given by the relation—

$$H = \frac{6.72\sqrt{V}}{r} \text{ gauss}$$

Where V is the anode potential in volts and r is the anode radius in centimeters the effect of a non-parallel field may be observed. Once the FP-400 has been "calibrated," it may be used to explore other unknown magnetic fields.

PHASITRON

DESCRIPTION

The GL-2H21 is a phase-modulator tube for use in FM transmitters. It is intended for operation up to 500 kilocycles. As a modulator tube, the GL-2H21 makes possible the introduction of comparatively wide-phase excursions at audio-frequency rates in a crystal-controlled, radio-frequency carrier. The modulating circuit audio response is such that the tube has a wide-swing, frequency-modulated output.

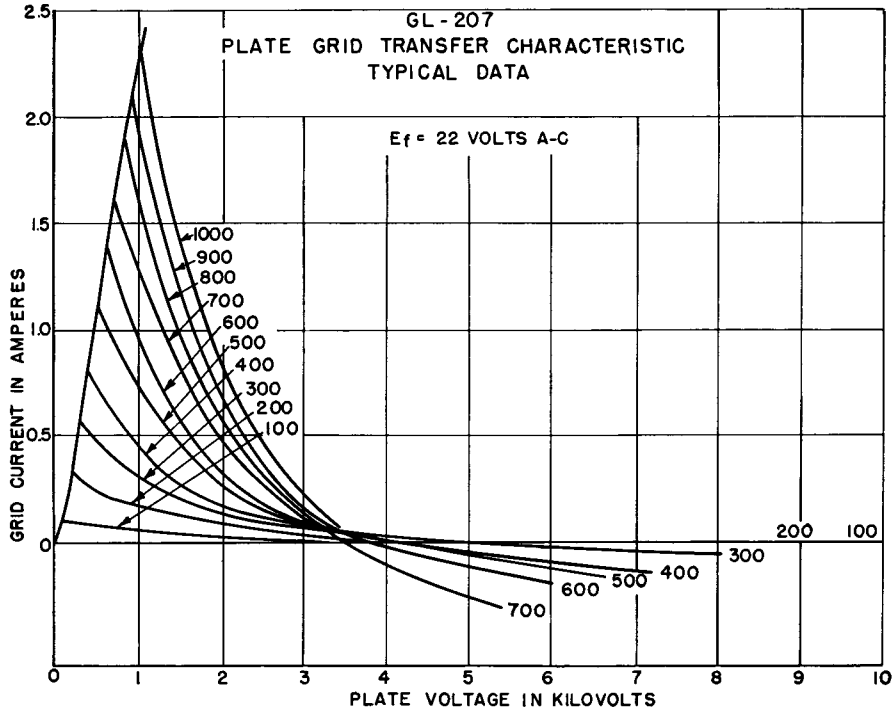
D-c grid current, approx.	0.17	0.12	0.09	0.2	ampere
Plate input				30	kilowatts
Plate dissipation				10	kilowatts
Peak r-f grid input voltage	1730	2050	2650		volts
Driving power, approx.	295	245	235		watts
Plate power output	6.5	10	15		kilowatts

\#\# Modulation, essentially negative, may be used if the positive peak of the audio-frequency envelope does not exceed the 115 per cent of the carrier conditions.

APPLICATION NOTES



The GL-207 can be operated at frequencies as high as 1.5 megacycles. The tube may be operated at higher frequencies provided the maximum values of plate voltage and power input are reduced as the frequency is raised (other maximum ratings are the same as shown under TECHNICAL INFORMATION). The tabulation below shows the highest percentage of maximum plate voltage and power input that can be used up to 20 megacycles for the various classes of service. Special attention should be given to adequate ventilation of the bulb at these frequencies.

Frequency				1.5	7.5	20	megacycles
Percentage of maximum rated plate voltage and plate input							
Class B				100	85	76	per cent
Class C plate modulated				100	75	50	per cent
Class C unmodulated				100	75	50	per cent
Plate series protective resistors							
Series resistor	25	50	200	250	275	300	ohms

THYRATRON

DESCRIPTION

The GL-414 is a hot-cathode, mercury-vapor all-metal thyratron.

The low voltage-drop characteristic and high efficiency of mercury tubes are combined in the GL-414 with the mechanical strength and ease of installation inherent in the all-metal design. These features result in a tube especially satisfactory for industrial applications.

IGNITRON

DESCRIPTION

The GL-427 is a small glass, air-cooled ignitron tube which combines the advantages of simple construction and visibility of operation. It is designed primarily for demonstrating the unique and interesting characteristics of ignitors used to initiate a cathode spot. The sturdy construction makes it particularly applicable to classroom demonstrations or student experiments. A red glass filter will be found to be a convenient aid in observing ignitor operation.

TECHNICAL INFORMATION

These data are for reference only. For design information refer to specifications.

GENERAL CHARACTERISTICS

Number of electrodes	3	
Electrical		
Typical arc drop	10–15	volts
Type of cooling		
Free-air circulation		
Average anode current	5	amperes
Ambient temperature	25	centigrade
Condensed mercury temperature	100	centigrade
Forced-air circulation†		
Average anode current	10	amperes
Ambient temperature	25	centigrade
Condensed mercury temperature	100	centigrade

†An ordinary desk fan will provide sufficient cooling for most uses.

THYRATRON

DESCRIPTION

The GL-502-A is an inert-gas-filled, double-grid thyratron with negative control characteristics. The control characteristic of this tube is independent of ambient temperature over a wide range. It has high sensitivity characteristics because the grid current is low enough to permit the use of a high resistance in the grid circuit. Because of its low grid-anode capacitance, the GL-502-A is relatively unaffected by line-voltage surges. The small size and weight of this thyratron are features which adapt it to applications where space and weight are important factors.

PLIOTRON

DESCRIPTION

The 807 is a beam power transmitting tube of the heater-cathode type having a maximum plate dissipation rating of 30 watts (ICAS). The high power sensitivity of this tube makes it especially useful in frequency-multiplier service where high harmonic output is essential. The 807 may also be used as a crystal oscillator and buffer amplifier in medium-power transmitters using up to a half-kilowatt input. Neutralization is generally unnecessary in adequately shielded circuits.

†Averaged over any audio-frequency cycle of sine-wave form.
+Modulation, essentially negative, may be used if the positive peak of the audio-frequency envelope does not exceed 115 per cent of the carrier conditions.
ϕ Subscript (2) indicates that grid current flows during some part of input cycle.
¶ Heater voltage fluctuations should not exceed +10 or −5 per cent from the rated value.
‡Driver stage should be capable of supplying the grids of the Class AB_2 stage with the specified peak values at low distortion. The effective resistance per grid circuit of the Class AB_2 stage should be kept below 500 ohms and the effective impedance of the highest desired response frequency should not exceed 700 ohms.
§With zero-impedance driver and perfect regulation, plate circuit distortion does not exceed 2 per cent. In practice, plate-voltage regulation, positive grid voltage regulation, and grid bias regulation should not be greater than 5 per cent, 5 per cent, and 3 per cent, respectively.
◆At crest of a-f cycle with modulation factor of 1.0.
△Connected to modulated plate-voltage supply.

APPLICATION NOTES

The GL-807 can be operated at frequencies as high as 60 megacycles. The tube may be operated at higher frequencies provided the maximum values of plate voltage and power input are reduced as the frequency is raised. (Other maximum ratings are the same as shown under TECHNICAL INFORMATION.) The tabulation below shows the highest percentage of maximum plate voltage and power input that can be used up to 125 megacycles for the various classes of service. Special attention should be given to adequate ventilation of the bulb at these frequencies.

Frequency	60	80	125	megacycles

PLIOTRON

DESCRIPTION

The GL-810 is a high-mu tube with a typical power output of 475 watts (ICAS) for Class C telegraph service. Because of its high perveance the tube can be operated at high plate efficiency with low driving power and relatively low plate voltage. The heavy duty filament, shielded at each end conserves input power by eliminating bulb bombardment and stray electrons. The plate and grid leads are brought out to terminals at the top and side of the bulb respectively—a design which provides very short internal leads, low internal lead inductance, and permits compact high-frequency circuits.

DESCRIPTION

GL-833-A is a three-electrode transmitting tube of the high-mu type for use as a radio-frequency amplifier, oscillator, and Class B modulator. Because of its high perveance, the 833-A can be operated at high plate efficiency with low driving power.

Designed in a new way with post terminals which provide a sturdy structure and make bases unnecessary, the 833-A has a minimum amount of insulation within the tube. The anode is supported directly from its post terminal at the top of the tube. Short, heavy-current leads are used to connect the anode and the grid to their respective terminals in order to carry the high circulating r-f current at the high frequencies and to minimize internal lead inductance.

As a result of its construction, the 833-A provides exceptional efficiency at high frequencies. It can be operated in Class C telegraph service with maximum input of 2000 watts at frequencies as high as 30 megacycles, and with reduced input at frequencies as high as 75 megacycles.

Plate power output, approx	1000	1440	1600				watts

*Forced-air cooling required at these conditions of operation. When forced-air cooling is required an air flow of 40 cfm from a two-inch diameter nozzle directed vertically downward on bulb between grid and plate seals is required. Bulb temperature between grid and plate seals must not exceed 145 C. For conditions of operation where forced-air cooling is not required, adequate free circulation of air around the tube is necessary for satisfactory operation.

†Averaged over any audio-frequency cycle of sine-wave form.

‡For a-c filament supply.

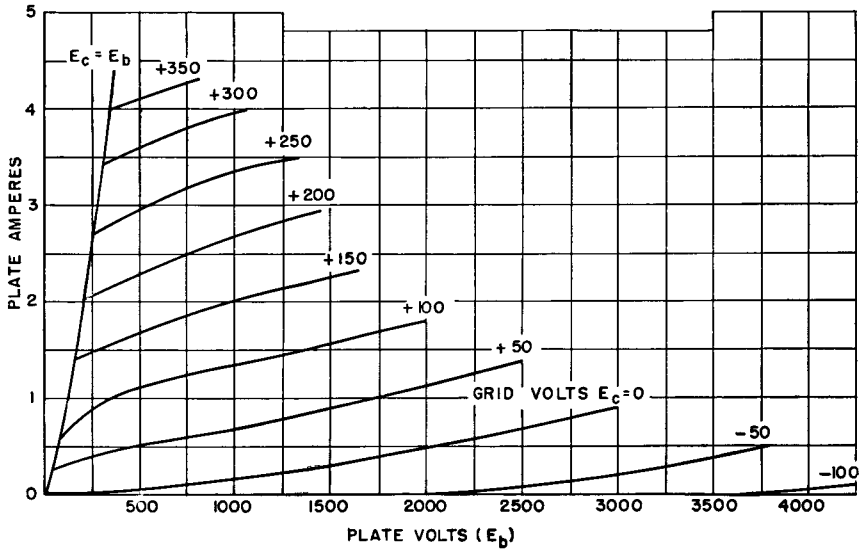
§At crest of audio-frequency cycle.

△Subject to wide variations depending on the impedance of the load circuit. High-impedance load circuits require more grid current and driving power to obtain the desired output. Low-impedance circuits need less grid current and driving power, but plate circuit efficiency is sacrificed. The driving stage should have a tank circuit of good regulation and should be capable of delivering considerably more than the required driving power.

πObtained by grid resistor of value shown or by partial self-bias methods.

□Modulation, essentially negative, may be used if the positive peak of the audio-frequency envelope does not exceed 115 per cent of the carrier conditions.

#Obtained from fixed supply, by grid resistor (3500, 2650, 2400), or by cathode resistor (425, 380, 380).



APPLICATION NOTES

The GL-833-A can be operated at frequencies as high as 30 megacycles. The tube may be operated at higher frequencies provided the maximum values of plate voltage and power input are reduced as the frequency is raised (other maximum ratings are the same as shown above). The tabulation below shows the highest percentage of maximum plate voltage and power input that can be used up to 100 megacycles for the various classes of service. Special attention should be given to adequate ventilation of the bulb at these frequencies.

PHANOTRON

DESCRIPTION

This half-wave, mercury-vapor rectifier is designed to withstand high peak inverse voltages and to conduct at low applied voltages. The construction minimizes the danger of bulb cracks caused by corona discharge. An edgewise-wound ribbon filament provides a large emission reserve and improved life.

Two 866-A/866's operating in a full-wave rectifier are capable of delivering to the input of a choke-input filter a rectified voltage of 3180 volts at 0.5 ampere with good regulation.

PHANOTRON

DESCRIPTION

The GL-869-B is a half-wave, mercury-vapor rectifier tube for use in broadcast transmitters and other applications where high d-c voltages are required. Economy of operation and high over-all efficiency result from several unique design features incorporated in this tube. The design of cathode allows the further advantage of operation with either in-phase or quadrature filament excitation. In quadrature operation the filament and anode voltages are approximately ninety degrees out of phase with each other. Such an arrangement, allowing uniform utilization of the cathode, results in greater uniformity of characteristics than is possible with other methods.

GLOW TUBES

DESCRIPTION

A glow tube is a cold-cathode, gas-discharge tube in which no means is provided for controlling the unidirectional current flow. (NEMA definition). This type of tube is also known as a voltage-regulator tube, a name which describes its principal application.

Fundamentally, a glow tube consists of two electrodes, an anode and a cold cathode, in a partial atmosphere of inert gas or vapor. The emission is obtained from the cold cathode by virtue of a potential gradient at the cathode surface. This gradient literally pulls electrons out of the cathode. For this reason cathodes are sometimes coated with some material which has a low work function so that electrons are given off with comparative ease.

GENERAL OPERATION

Two types of discharge are possible in a glow tube. A glow discharge, which is a uniform glow covering all or part of the cathode surface, will occur when the current carried by the tube is low. Under these conditions the tube drop is essentially independent of the current. This is the condition under which glow tubes normally operate. The exact voltage drop across the tube depends upon the electrode spacing and the type and amount of gas used.

If the current through the tube is increased beyond a certain point the tube will go into a so-called arc discharge. Under these conditions a cathode spot rather than a uniform cathode glow appears on the cathode and the tube drop decreases to a rather low value (10-20 volts). Although some glow tubes are designed to operate as arc-discharge tubes, the majority of glow tubes must not be operated so that an arc discharge takes place, as the life of the tube will be materially shortened.

TECHNICAL INFORMATION

These data are for reference only. For design information refer to specifications.

GENERAL CHARACTERISTICS

Tube Type Number	GL-OA3/VR-75, GL-OB3/VR-90 GL-OC3/VR-105, GL-OD3/VR-150	GL-874
Type of voltage-regulator tube	Glow discharge	Glow discharge
Cathode	Cold type	Cold type
Maximum over-all length	4 1/8 inches	5 3/8 inches
Maximum seated height	3 9/16 inches	4 3/4 inches
Maximum diameter	1 9/16 inches	2 1/16 inches
Base	Small shell octal 6-pin	Medium 4-pin bayonet
Net weight, approx.	2 ounces	2 ounces
Shipping weight, approx.	3 pounds	3 pounds

MAXIMUM RATINGS

Tube Type Number	GL-OA3/VR-75	GL-OB3/VR-90	GL-OC3/VR-105	GL-OD3/VR-150	GL-874
Minimum d-c anode supply voltage	105	125	133	185	125 volts
D-c operating Current:					
Maximum*	40	30	40	40	50 milliamperes
Minimum	5	10	5	5	10 milliamperes

D-c operating voltage, approx.	75	90	105	150	90 volts
D-c operating current, continuous	5 to 40	5 to 30	5 to 40	5 to 40	10 to 50 milliamperes
Regulation 5 to 30 milliamperes	3	4	1	2	volts
Regulation 5 to 40 milliamperes	5	–	2	4	volts
Ambient temperature range	−55 to +90	−55 to +90	−55 to +90	−55 to +90	centigrade

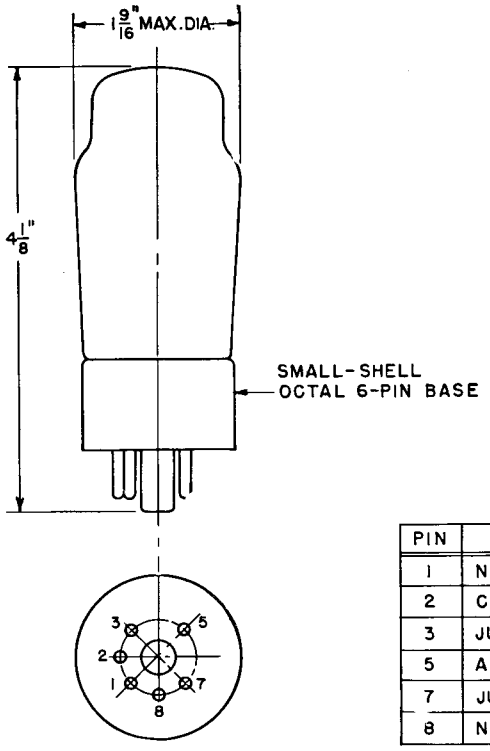
**Sufficient resistance must always be used in series with the tube to limit the current through it to this value.*

DEFINITIONS OF RATINGS

D-c Anode Supply Voltage, Minimum

This is the minimum value of voltage that the voltage supply must be capable of applying to the glow tube.

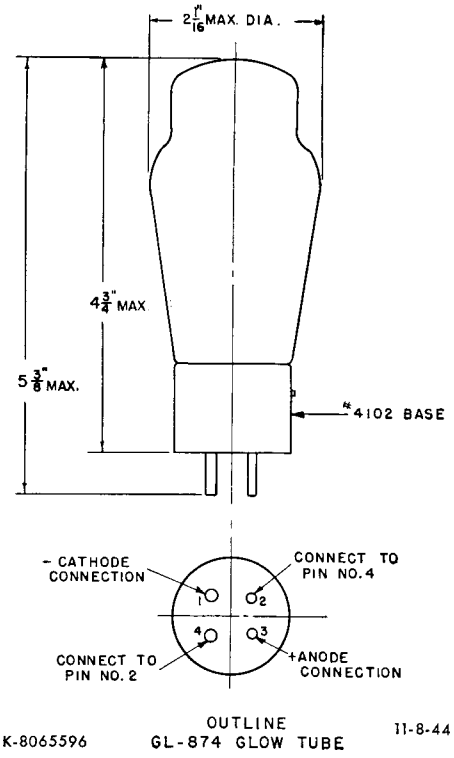
D-c Operating Current



These values of maximum and minimum current indicate the range over which the glow tube will operate satisfactorily. Operation below the minimum current will cause erratic regulation and operation above maximum current will result in short life and erratic regulation.

Regulation

The regulation voltage is the maximum variation in voltage drop across the glow tube. It is calculated as the difference between the voltage drop obtained at the maximum current and the voltage drop obtained at the minimum current.



Ambient Temperature Range

This temperature range indicates the maximum and minimum temperatures at which satisfactory operation may be obtained.

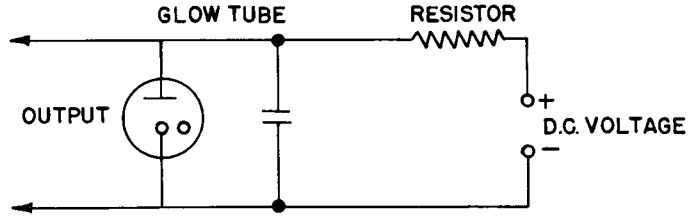
GL-874 GLOW TUBE

APPLICATION CIRCUITS

The most common use of the glow tube is as a voltage regulating device.



K-8639684 Fig. 1—Voltage-Regulated Power Supply Circuit 9-25-44

Fig. 1 above illustrates a voltage-regulated power supply circuit incorporating a glow tube as a voltage stabilizer. (*Most glow tubes are provided with a jumper wire connected internally. This is usually employed as a switch, and is wired in series with the primary of the transformer supplying power to the glow tube. When the tube is removed from the socket the power supply circuit is automatically shut off.)

Such a circuit is an inexpensive means of providing a regulated voltage within the capabilities of a tube for such applications. The series resistance must be of a value that will limit the current through the glow tube to the maximum rated current. It is also desirable to furnish a high enough voltage from the d-c supply so that the current through the glow tube does not drop below the minimum rating.

Glow tubes may be used in series to provide higher regulated voltages than are available from one tube. These tubes need not be the same type, the only requirement being that the current must be limited so that it falls within the operating range of the combination. For example, if a GL-OA3/VR75 and a GL-OB3/VR90 are used in series, the current must be limited to 30 milliamperes maximum. Operation of glow tubes in parallel is not recommended.

A second application of the glow tube is the relaxation oscillator illustrated in Fig. 2.

K-8639685 Fig. 2—Relaxation Oscillator Circuit 9-25-44

In this type of circuit, a current charges a capacitor. In parallel with the capacitor is a glow tube, which will break down when the voltage on the capacitor reaches the voltage breakdown point of the glow tube. The frequency of this action may be varied by changing the capacitance or type of glow tube.

#Circuits shown in ETI-176 are examples of possible tube applications and the description and illustration of them does not convey to the purchaser of tubes any license under patent rights of General Electric Company.

INSTALLATION AND OPERATION

Sufficient resistance must always be used in series with each of these tubes to limit the current through the tube to the maximum rated value under continuous (steady state) operating conditions. During the interval of 5 to 10 seconds which may be required for the regulated tubes in associated equipment to warm up and draw plate current, a maximum current of 100 milliamperes is permissible provided each such starting period is followed by a steady-state operating period of at least several minutes. Unless this precaution is observed, tube performance will be impaired.

In voltage-regulator tubes of the glow-discharge type, regulation is somewhat dependent on past operating conditions. For example, the regulation value of a tube operated for a protracted period at 5 milliamperes and then changed to 35 millliamperes may be somewhat different from the value that will be obtained after a long period of operation at 35 milliamperes. Likewise, the regulation value may change somewhat after a long idle period.

PLIOTRON

DESCRIPTION

The 880 is a three-electrode power tube designed for use as a radio-frequency amplifier, oscillator, or Class B modulator. The plate is water-cooled and is capable of dissipating 12 to 20 kilowatts. The design of the terminal mount connections and the introverted anode minimize lead inductance and make the tube particularly suitable for high-frequency applications.

PLIOTRON

DESCRIPTION

The GL-891 is a three-electrode transmitting tube of the double-filament type for use as a radio-frequency power amplifier, oscillator, Class A modulator and Class B modulator. The construction of the filament permits operation from two-phase or single-phase alternating current as well as from direct current, for all classes of service. The plate is water-cooled and is capable of dissipating 4 to 7.5 kilowatts depending on the service in which the tube is used.

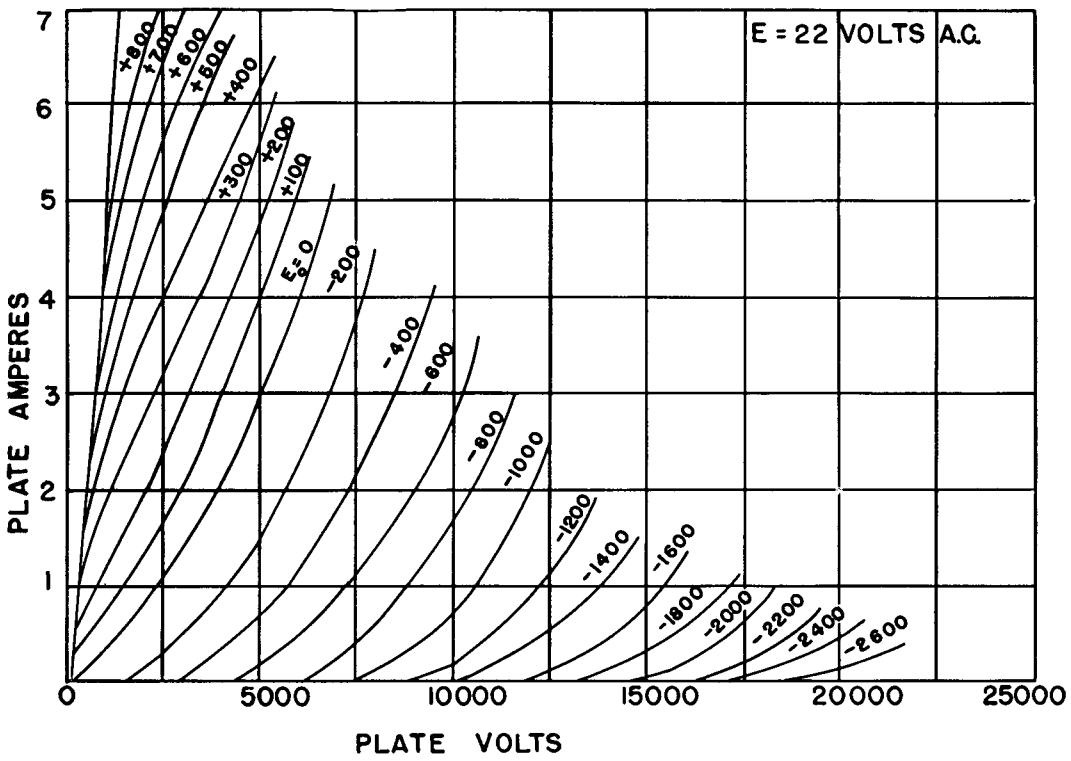
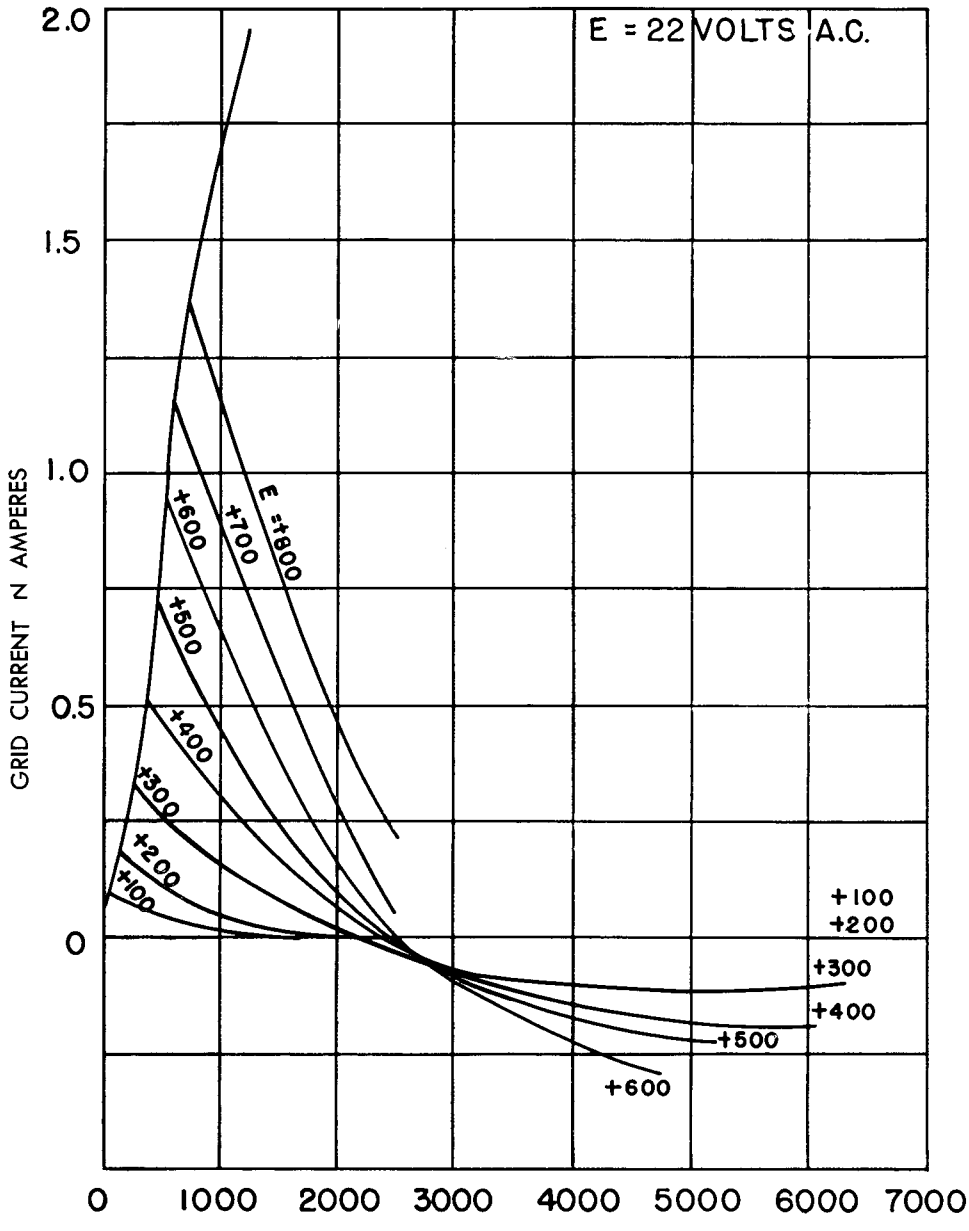
**With d-c filament supply.
#At crest of a-f cycle with modulation factor of 1.0.
##Modulation essentially negative may be used if the positive peak of the audio-frequency envelope does not exceed 115 per cent of the carrier conditions.



APPLICATION NOTES

GL-891 can be operated at maximum ratings in all classes of service at frequencies as high as 1.6 megacycles. The tube may be operated at higher frequencies provided the maximum values of plate voltage and power input are reduced as the frequency is raised. (Other maximum ratings are the same as shown under MAXIMUM RATINGS and TYPICAL OPERATING CONDITIONS.) The tabulation shows the highest percentage of maximum plate voltage and power input that can be used up to 20 mc for the various classes of service. Special attention should be given to adequate ventilation of the bulb at these frequencies.

Frequency	1.6	7.5	20	megacycles



Maximum permissible percentage of maximum rated plate voltage and plate input:

Class B telephony	100	82	72	per cent
Class C (telephony, plate modulated)	100	75	65	per cent
(telegraphy)	100	75	50	per cent

PLIOTRON

DESCRIPTION

The 892 is a three-electrode pliotron of the double-filament type for use as a radio-frequency power amplifier, oscillator, and Class B modulator. The construction of the filament permits operation from two-phase or single-phase alternating current as well as from direct current, for all classes of service. The plate is water-cooled and is capable of dissipating 6.6 to 10 kilowatts.

TECHNICAL INFORMATION

These data are for reference only. For design information refer to specifications.

GENERAL CHARACTERISTICS

Number of electrodes	3

PLIOTRON

DESCRIPTION

The GL-893-A is a three-electrode, water-cooled vacuum tube designed for use as a radio-frequency amplifier, oscillator, or Class B modulator. A particular advantage of this tube is the unique construction of the filament which permits operation from single-phase, three-phase, or six-phase alternating current, or from direct current, for all classes of service.

TECHNICAL INFORMATION

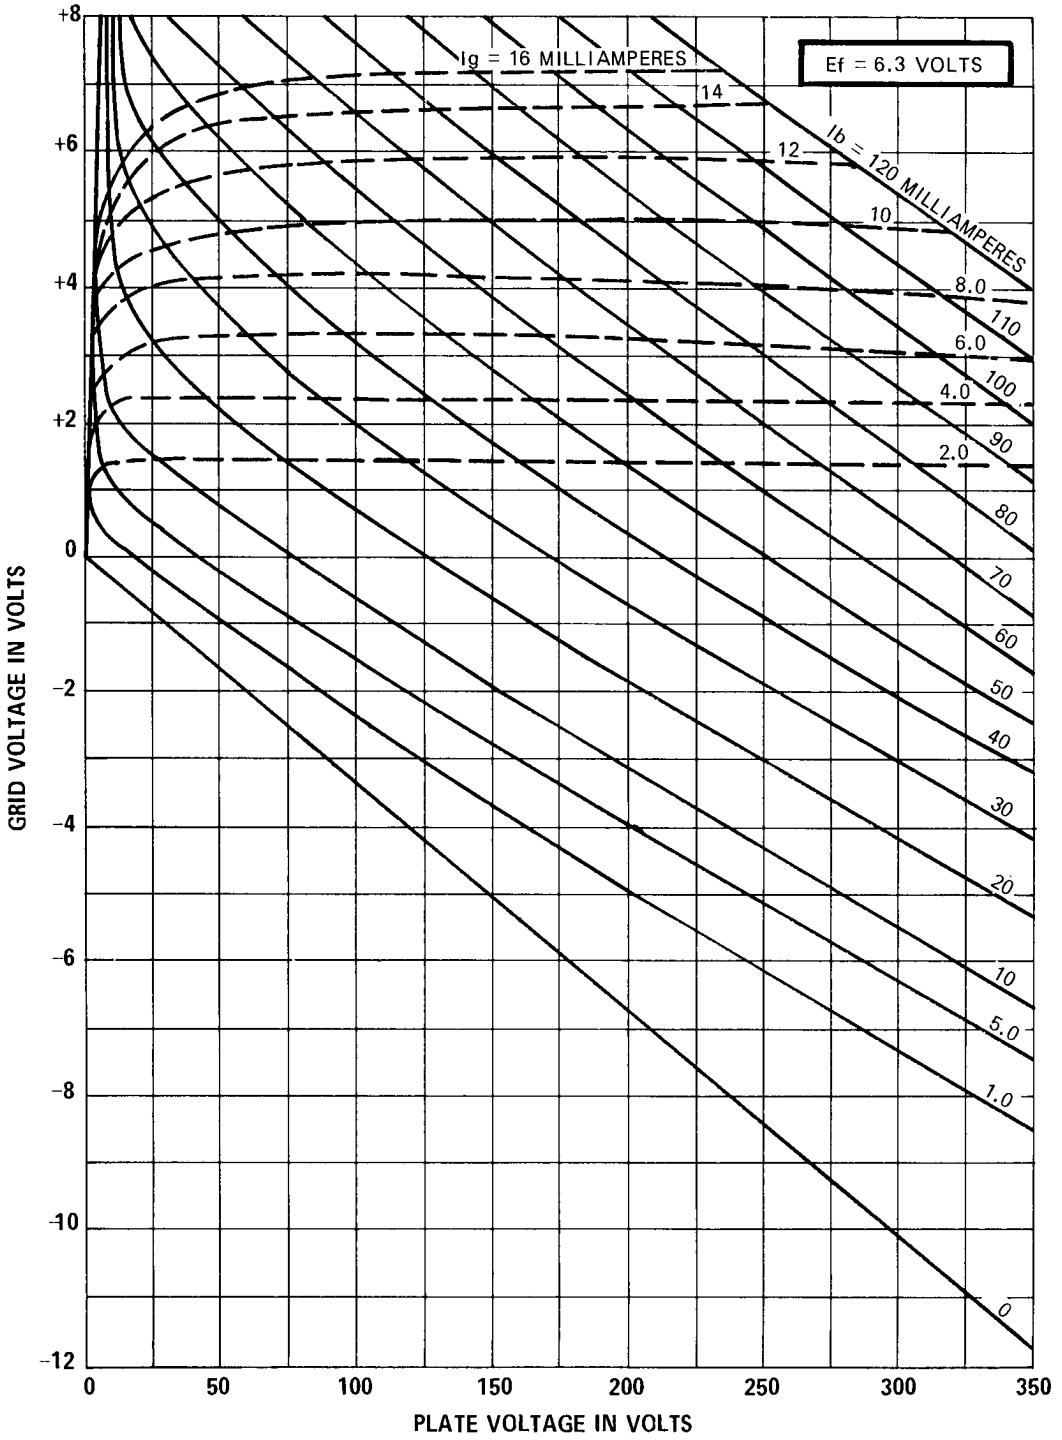
Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron device of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

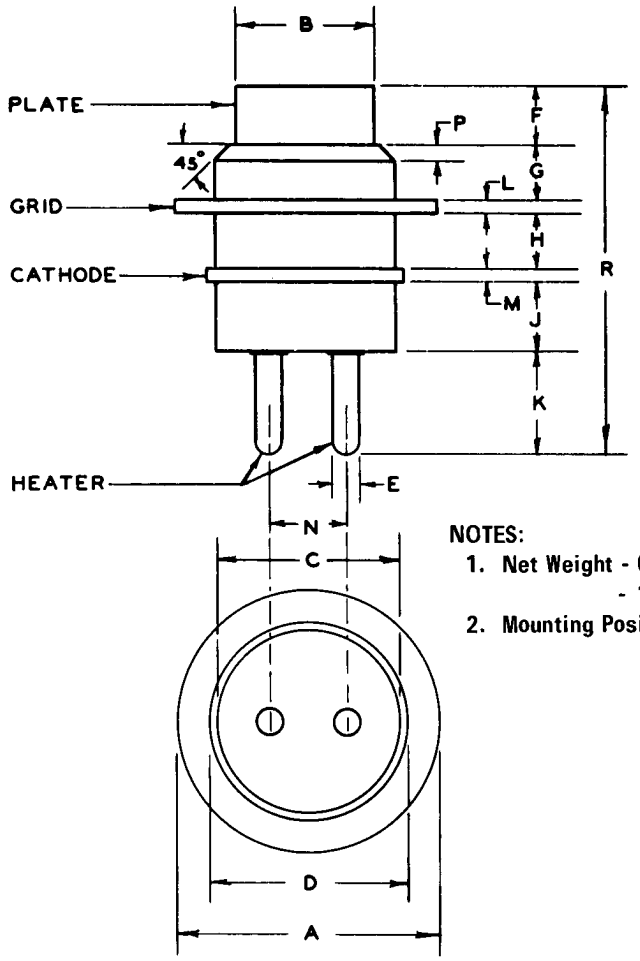
The device manufacturer chooses these values to provide acceptable serviceability of the device, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the device under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any device under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the device under consideration and of all other electron devices in the equipment.



NOTES

▲ For specific recommendations concerning higher temperature operation, contact your General Electric sales representative.



♦ This assumes no thermal heat sinking to any insulator.

The devices and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of devices by General Electric Company conveys any license under patent claims covering combinations of these devices with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of these devices with other devices or elements by any purchaser or others.

—PRODUCT INFORMATION—

Planar Triode

GE14501

The GE14501 is a high-mu triode of ceramic-and-metal planar construction intended for use as an oscillator or radio-frequency power amplifier in the ultra-high- frequency range. This tube is especially suited for use where unfavorable conditions of mechanical shock, mechanical vibration, and high temperature are encountered. The outline of this device is ideally suited for coaxial type circuitry.

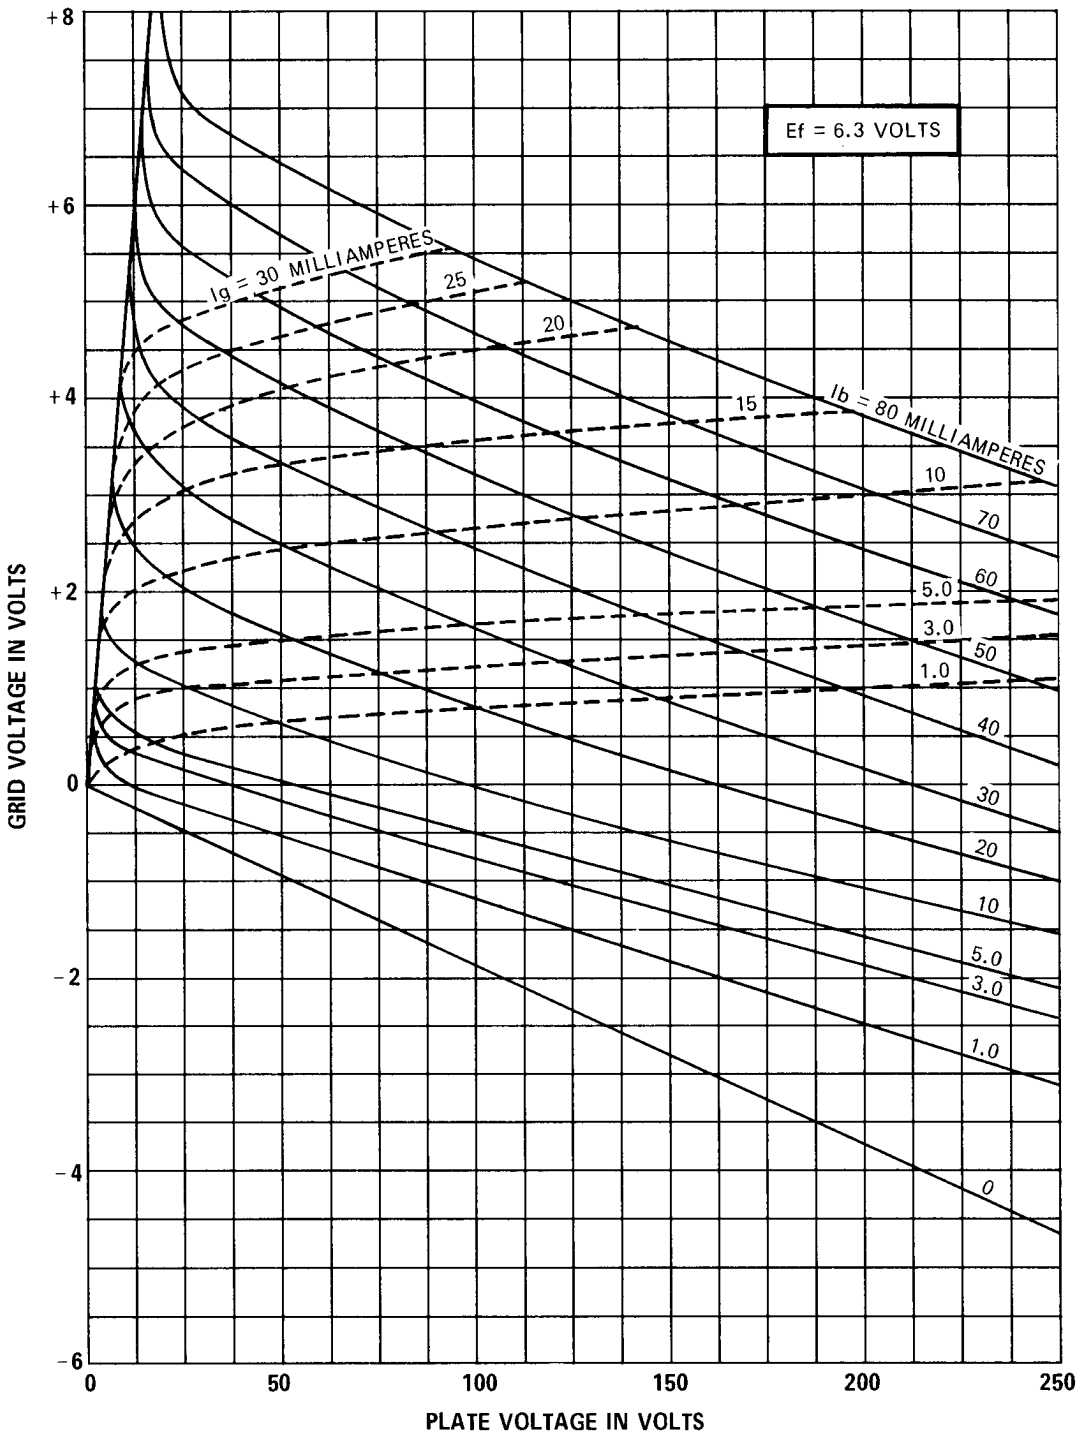
Envelope Temperature at Hottest Point ♦	250	°C
Temperature Differential Between Two Adjacent Electrodes ▲	75	°C
Mechanical Vibration (20-2000 Hz Sinusoidal)	10	G Peak

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron device of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

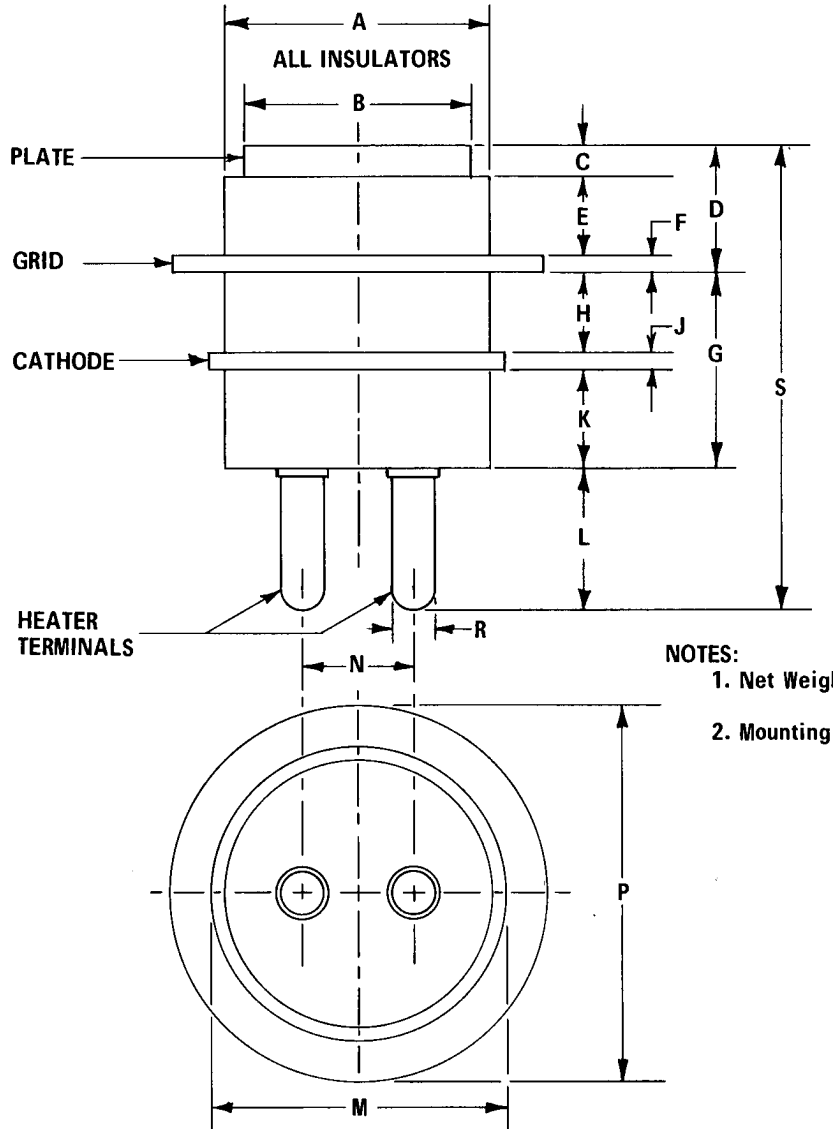
The device manufacturer chooses these values to provide acceptable serviceability of the device, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the device under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any device under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the device under consideration and of all other electron devices in the equipment.



NOTES

♦ For specific recommendations concerning higher temperature operation, contact your General Electric sales representative.



▲ This assumes no thermal heat sinking to any insulator.

The devices and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of devices by General Electric Company conveys any license under patent claims covering combinations of these devices with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of these devices with other devices or elements by any purchaser or others.

Planar Triode

GE14811

The GE14811 is a planar triode intended for use as a plate-pulsed, C-band oscillator at relatively low plate voltage levels. It is useful in medium power applications where very short pulses are required, such as radar altimeters and beacons.

—PRODUCT INFORMATION—

Planar Triode

GE16411

The GE16411 is a high-mu-triode of ceramic-and-metal planar construction intended for use as an oscillator or radio-frequency power amplifier in the ultra-high-frequency range. This tube is especially suited for use where conditions of extreme mechanical shock, mechanical vibration, and high temperature are encountered. The rugged bonded-heater construction also provides fast cathode warm-up.

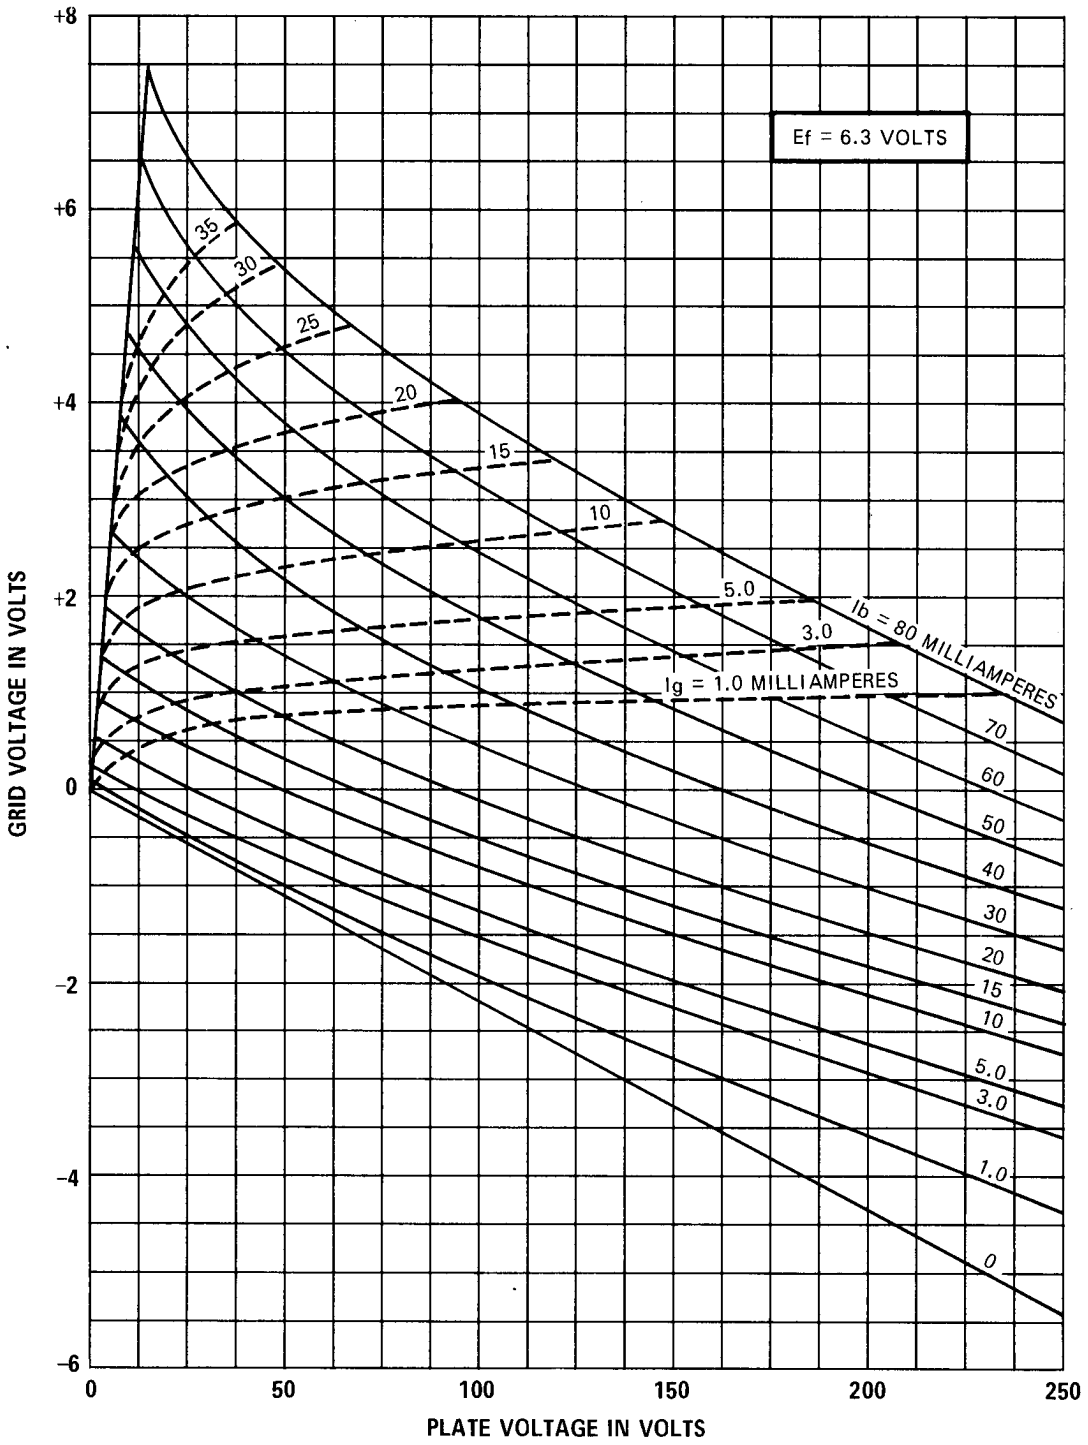
Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron device of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

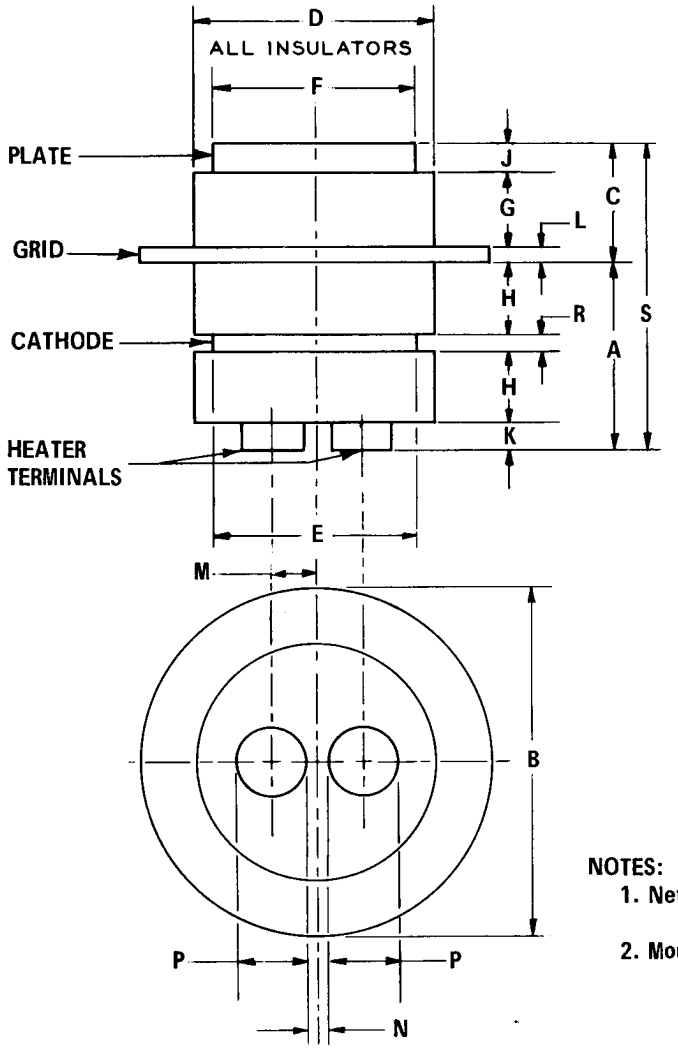
The device manufacturer chooses these values to provide acceptable serviceability of the device, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the device under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any device under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the device under consideration and of all other electron devices in the equipment.



NOTES

▲ For specific recommendations concerning higher temperature operation, contact your General Electric sales representative.



□ This assumes no thermal heat sinking to any insulator.

The devices and arrangements disclosed herein may be covered by patents of General Electric Company or others. Peak Power Output, Approximate	675	Watts

NOTES

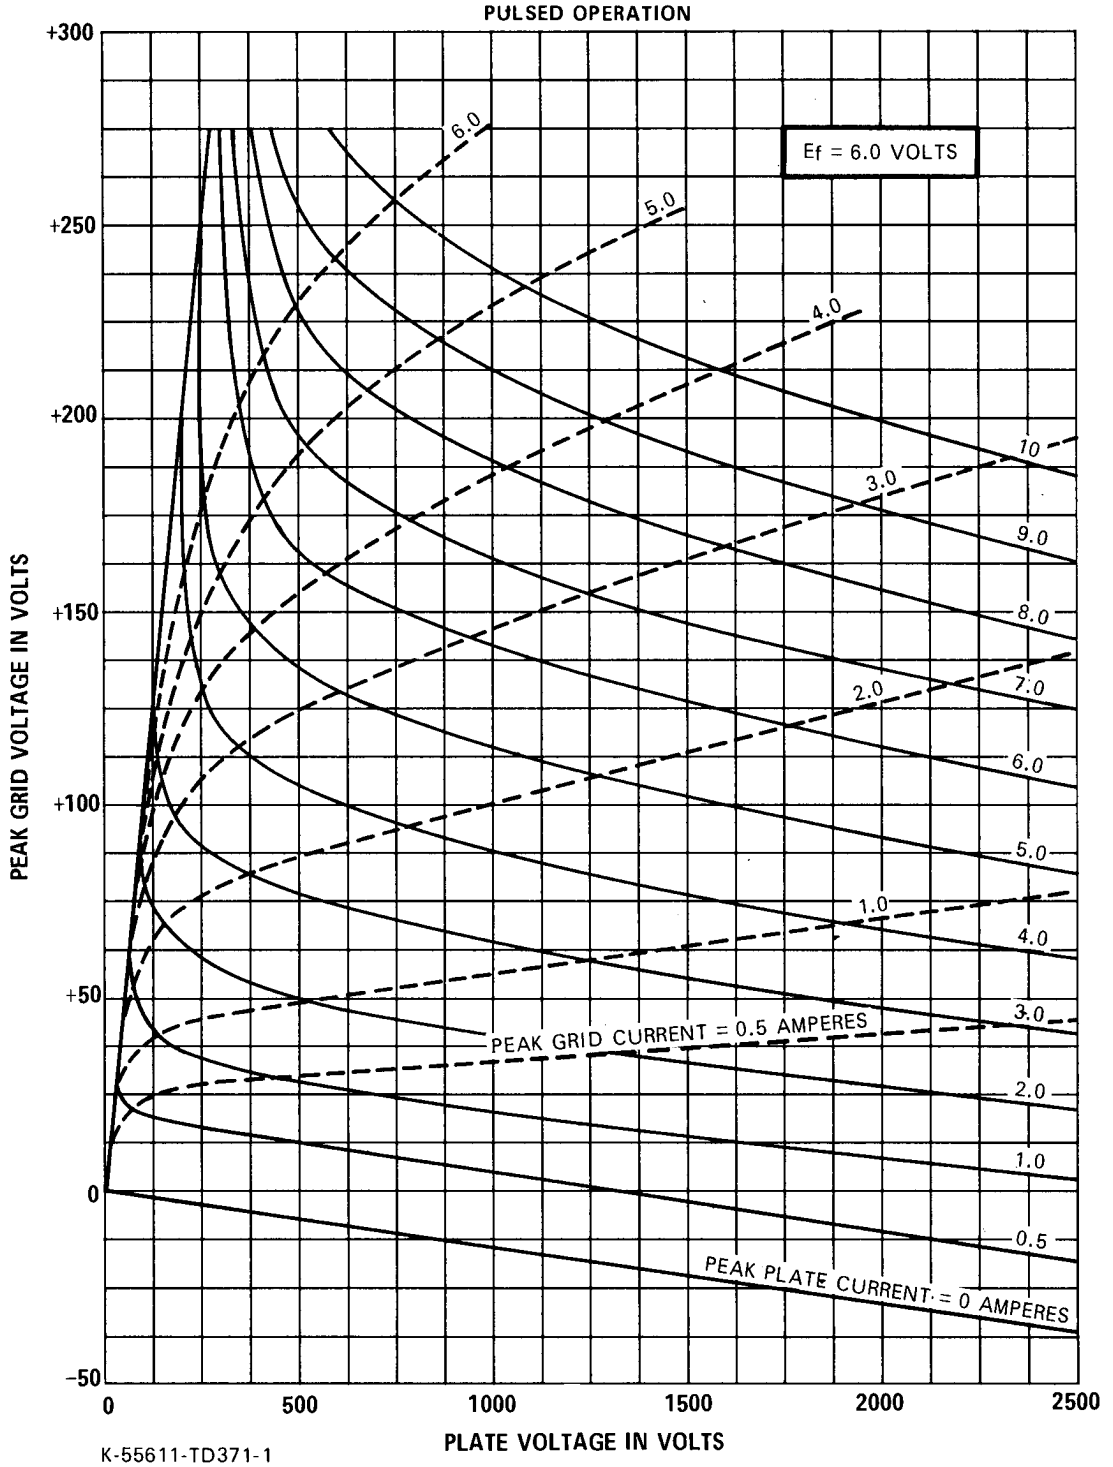
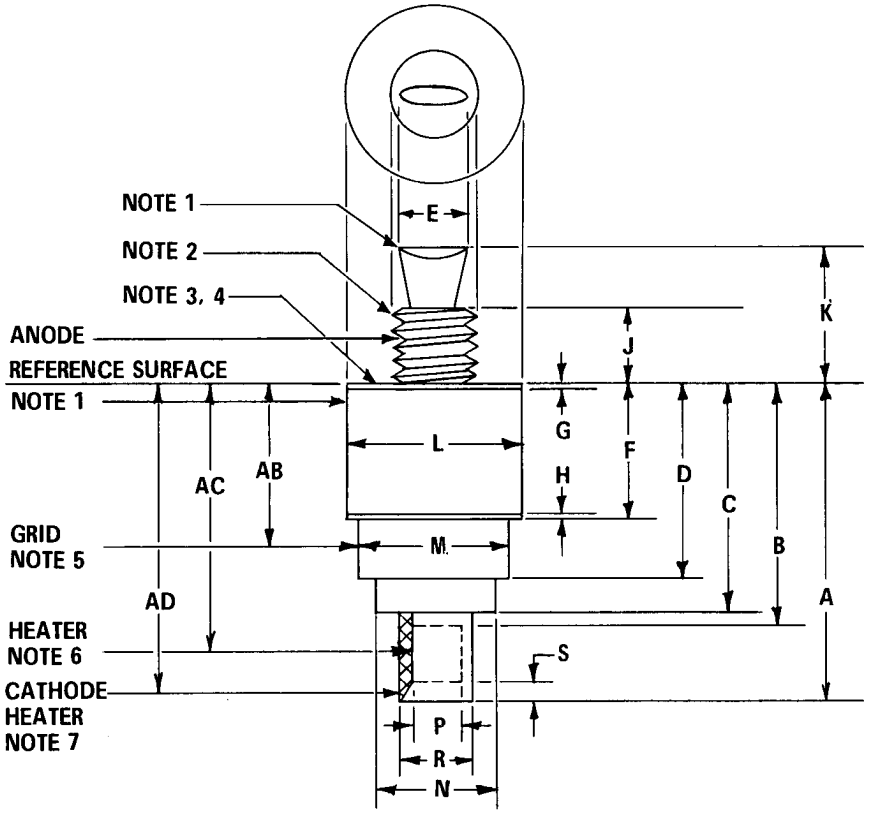
★ The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance. When used at low peak plate current the heater voltage should be reduced for longer life.

● Heater current of a bogey tube at Ef = 6.0 volts.



♦ Without external shield.

▲ With adequate heat sink.



■ The impedance of the plate supply should be such as to limit the plate current to 10 times the normal operating plate current if the tube is considered a short circuit.

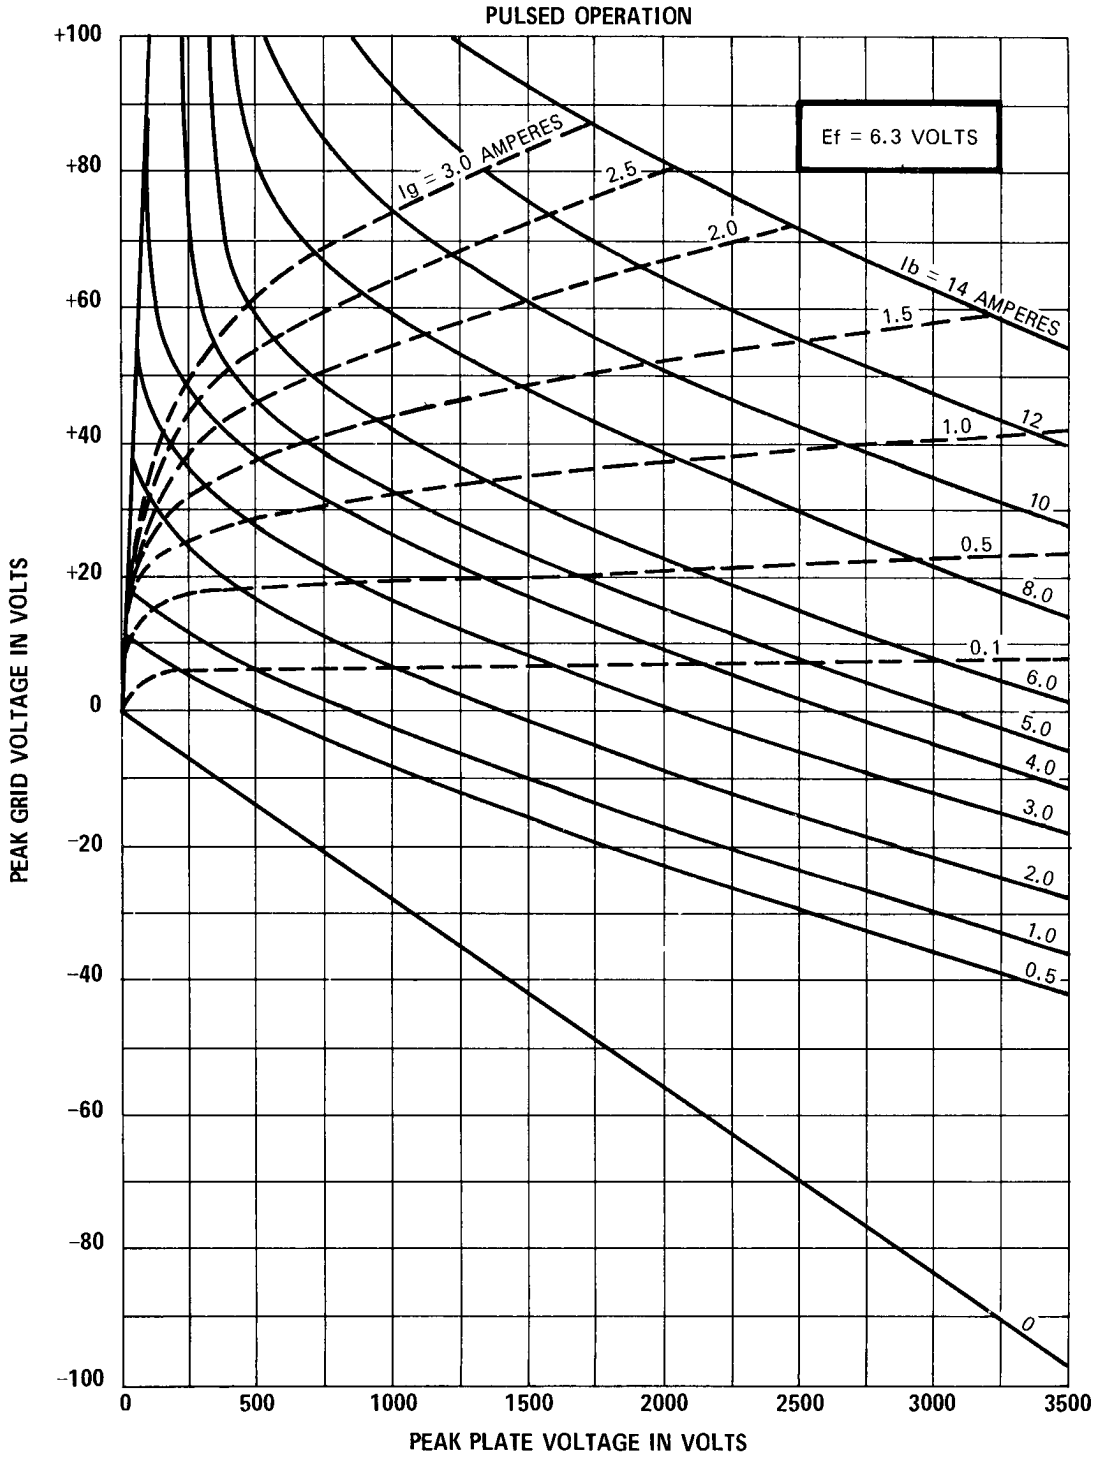
Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron device of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The device manufacturer chooses these values to provide acceptable serviceability of the device, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the device under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any device under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the device under consideration and of all other electron devices in the equipment.

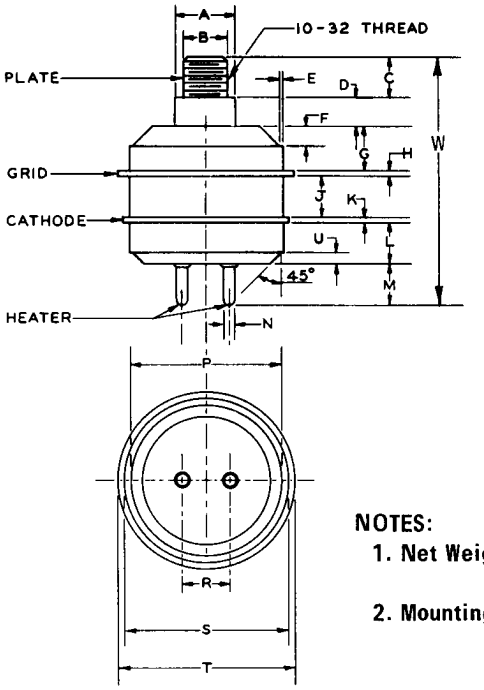
NOTES

§ In any 5 millisecond interval.



⊕ The regulation and/or series plate supply impedance must be such as to limit the peak current, with the tube considered a short circuit, to a maximum of 10 times the maximum plate current rating.

▲ For specific recommendations concerning higher temperature operation, contact your General Electric sales representative.



♦ This assumes no thermal heat sinking to any insulator.

The devices and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of devices by General Electric Company conveys any license under patent claims covering combinations of these devices with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of these devices with other devices or elements by any purchaser or others.

PHOTOTUBE

DESCRIPTION

The GL-917 is a two-electrode high-vacuum phototube for measurement and relay applications. It has high sensitivity in the red and infrared regions of the spectrum. Construction affords high resistance to leakage current between electrodes, with resultant stability of operation and permanence of calibration. The anode of the GL-917 is connected to the top cap, while in the GL-919 the cathode is connected to the top cap. As a result of this reversal of connections, the GL-917 may be used in series with the GL-919 with resultant very small leakage current and high overall sensitivity.

TECHNICAL INFORMATION

These data are for reference only. For design information refer to specifications.

PHOTOTUBE

DESCRIPTION

The GL-931-A is an eleven-electrode vacuum phototube unique in that the photo-current produced at the cathode is multiplied many times by secondary emission occurring at successive dynodes within the tube. This tube can multiply feeble currents produced by weak illuminations as much as 200,000 times. This feature combined with its high sensitivity, low-noise level, low-dark current, and freedom from distortion renders the GL-931-A very useful for relays and in applications involving low-light levels.

THYRATRON

DESCRIPTION

The GL-2050 is a small, double-grid, inert-gas-filled thyratron designed for grid-controlled rectifier service. The control characteristic is independent of ambient temperature over a wide range. The tube is not appreciably affected by line-voltage surges because of the low grid-to-anode capacitance. High sensitivity, the result of low grid current which allows the use of high resistance in the grid circuit, permits operation of the GL-2050 thyratron from a vacuum-type phototube.

TECHNICAL INFORMATION

These data are for reference only. For design information refer to specifications.

GENERAL CHARACTERISTICS

Number of electrodes	4	
Electrical		
Cathode—Indirectly heated type		
Voltage	6.3	volts
Current, approx	0.6	ampere
Heating time, minimum	10	seconds
Peak voltage drop, approx	8	volts
Grid resistors*		
Minimum	0.01	megohm
Maximum	10	megohms
Anode to control-grid capacitance, approx	0.26	micromicrofarad

**When this tube is operated with an alternating anode voltage and a high value of grid-circuit resistance, the grid-anode capacitance should be made as small as possible by placing the grid resistor directly at the socket terminal, by connecting pins 4 and 8 together at the socket, and by using a close fitting bulb shield connected to the cathode terminal.*

Maximum	10	megohms
Anode to control-grid capacitance, approx	0.2	micromicrofarad

When this tube is operated with an alternating anode voltage and a high value of grid-circuit resistance, the grid-anode capacitance should be made as small as possible by placing the grid resistor directly at the socket terminal, by connecting pins 4 and 8 together at the socket, and by using a close fitting bulb shield connected to the cathode terminal.

TRIODE

The GL-5518 is a three-electrode transmitting tube designed for use as a Class C radio-frequency amplifier. This tube is particularly well adapted to use in a grounded-grid circuit. The anode is forced-air-cooled, and capable of dissipating 4000 watts. The cathode is a pure-tungsten filament. Maximum ratings apply up to 110 megacycles.

IMAGE ORTHICON

The GL-5820 is a television camera tube for outdoor and studio pickup use in which exceptionally high sensitivity is combined with a spectral response approaching that of the eye. It is very stable in performance at all incident light levels on the object ranging from bright sunlight to a deep shadow (several thousand foot-candles to one foot-candle or less). Commercially acceptable pictures can be obtained at incident light levels greater than about 10 foot-candles.

The GL-5820 has a photocathode characterized by a spectral response with high blue and high green sensitivity, very good yellow sensitivity, and good red sensitivity. It has practically no infrared sensitivity. This particular characteristic of the response permits portrayal of colors in nearly their true tonal gradation since it prevents any color-masking by infrared.

KENOTRON

PLATE DISSIPATION—800 WATTS
THORIATED-TUNGSTEN FILAMENT
RECTIFIER AND LIMITER DIODE

LOW VOLTAGE DROP
20 AMPERES AT 75 KILOVOLTS
1.25 AMPERES DC AT 40 KILOVOLTS

The GL-5973 is a two-electrode high-vacuum tube for use as a rectifier or surge-limiting diode. Design features include a thoriated-tungsten filament and a low voltage drop which enable the tube to carry high average currents.

In rectifier service the tube will operate at average currents as high as 1.25 amperes at 40,000 volts and one ampere at higher voltages. In limiter service ratings as high as 20 amperes at 75,000 volts apply. These ratings make the tube particularly suitable for use in radar as a charging diode to supply d-c power to magnetrons or as a limiter to restrict fault currents. Other applications include high-voltage power supplies in cable-testing service and smoke precipitators.

METAL AND CERAMIC
GAIN IN EXCESS OF 10

The GL-6251 is a four-electrode, water-and-forced-air-cooled transmitting tube for use as a power amplifier or oscillator in grounded-grid circuits with both grids maintained at radio-frequency ground potential. The output circuit is connected between the anode and the screen grid. The anode is capable of dissipating twenty-five kilowatts. The cathode is a thoriated-tungsten filament. Maximum ratings apply up to 220 megacycles.

In Class B grounded-grid broadband television amplifier service this tube has a useful synchronizing peak-power output of twenty-five kilowatts at 220 megacycles. Because of its ratings, the tube is also well adapted to use in dielectric-heating equipment.

High operating efficiency is assured because of the close spacing of the tube electrodes, the ring-seal construction, and the low-loss factor due to the silver-plated external parts and the ceramic insulator. The ring-seal design permits quick plug-in installation. In addition, the grounded-grid construction eliminates the necessity for neutralization in a properly designed circuit.

TUBES

GL-6283
TETRODE

RADIO-FREQUENCY AMPLIFIER CW SERVICE GROUNDED-GRID OPERATION

The GL-6283 is a reliable power tetrode that delivers useful output to 1250 megacycles or higher. This tube is particularly suitable for application in the final output or driver stage of military-communications systems.

As a Class B linear amplifier in the 225–400-megacycle range, the tube will deliver 110 watts of carrier power modulated up to 100 percent. Since a power gain of 20 may be realized, drive requirements are low—approximately 5 watts at carrier level.

FORCED-AIR COOLED METAL AND CERAMIC INTEGRAL RADIATOR

Operating as a Class C CW amplifier at 900 megacycles, the gain is approximately 15 at the 200-watt level.

Features of the GL-6283 include long life and reliability, high gain, high linearity, and resistance to shock and vibration.

These together with such design factors as an oxide-coated cathode, coaxial elements, and metal-ceramic construction make the tube well adapted to application in modern systems where performance and reliability are important.

* Because the temperature of the cathode is increased by back bombardment of electrons at UHF, required heater voltage for optimum life decreases with increasing frequency. The amount of heater-voltage reduction is dependent on operating conditions. However, this voltage should not be less than 5.5 volts.
† Represents maximum usable cathode current (plate current plus current to each grid) for any condition of operation.
‡ Measured with a 6-inch minimum diameter flat metal disk attached to the screen-grid ring. Control grid connected to the screen grid.
♦ Output capacitances measured between anode and screen grid. Control grid connected directly to screen grid.
§ Forced-air cooling to be applied before and during the application of any voltages.
**Provision must be made for unobstructed passage of cooling air between radiator fins and between the anode terminal and adjacent radiator fin.
♥Useful power output as measured in output-circuit load.
¶ Useful power output including power transferred from driver stage. Output circuit efficiency approximately 80 percent.
△Modulation essentially negative may be used if the positive peak of the envelope does not exceed 115 percent of the carrier conditions.

GL-6848
TETRODE

VHF-UHF **FORCED-AIR COOLED**
RING-SEAL CONSTRUCTION **METAL AND CERAMIC**
GROUNDED-GRID CIRCUIT

The GL-6848 is a four-electrode transmitting tube featuring a metal-and-ceramic envelope for use as a power amplifier or oscillator in grounded-grid circuits with both grids maintained at radio-frequency ground potential. The output circuit is connected between the anode and the screen grid. The anode is capable of dissipating 2 kilowatts. Cooling is accomplished by forced air with the radiator an integral part of the anode. The cathode is a unipotential thoriated-tungsten cylinder, heated by electron bombardment. Maximum ratings apply up to 800 megacycles, although higher frequency operation is possible.

In narrow band, Class C, grounded-grid, amplitude-modulated service, the GL-6848 has a useful carrier-power output in excess of one kilowatt. In Class C Telegraphy, it has a useful power output of 3.0 kilowatts of continuous power as an amplifier or oscillator.

Temperature at Any Other Point	200 Max C

Forced-air cooling to be applied before and during the application of any voltage. Air flow on heater-to-cathode seals must be maintained for one minute after removal of heater voltage. The air duct can be constructed so that air is forced along the anode seal and ceramic through the anode contact fingers to accomplish the anode ceramic and anode seal cooling. The volume of cooling air indicated is approximate only. Distribution of cooling air will vary with configuration of the cavity about the tube.

* The cathode of the GL-6848, because of transit-time effects which raise the temperature of the cathode, is subjected to considerable back bombardment in ultra-high-frequency service. The amount of heating due to bombardment is a function of the operating conditions and frequency, and must be compensated for by a reduction of the cathode power input to prevent overheating of the cathode with resulting short life. In any case it is important from a tube life standpoint to keep the cathode power at as low a level as possible consistent with required performance. Bombarder power should be monitored by a suitable wattmeter or DC voltmeter and milliammeter arrangement. For long life, the tube should be put in operation with about 180 watts bombarding power. After the circuit has been adjusted for proper tube operation, bombarding voltage should be reduced to a value slightly above that at which circuit performance is affected. Minor circuit readjustment may be necessary after the above adjustment. The procedure for determining proper bombarding power should be repeated periodically.

‡ Represents maximum usable cathode current.(plate current plus current to each grid) for any condition of operation.

§ Measured with complete isolation between cathode and plate.

¶ Output capacitance measured between anode and screen grid. Control grid connected directly to screen grid.

TUBE DEPARTMENT

GENERAL ELECTRIC

Owensboro, Kentucky

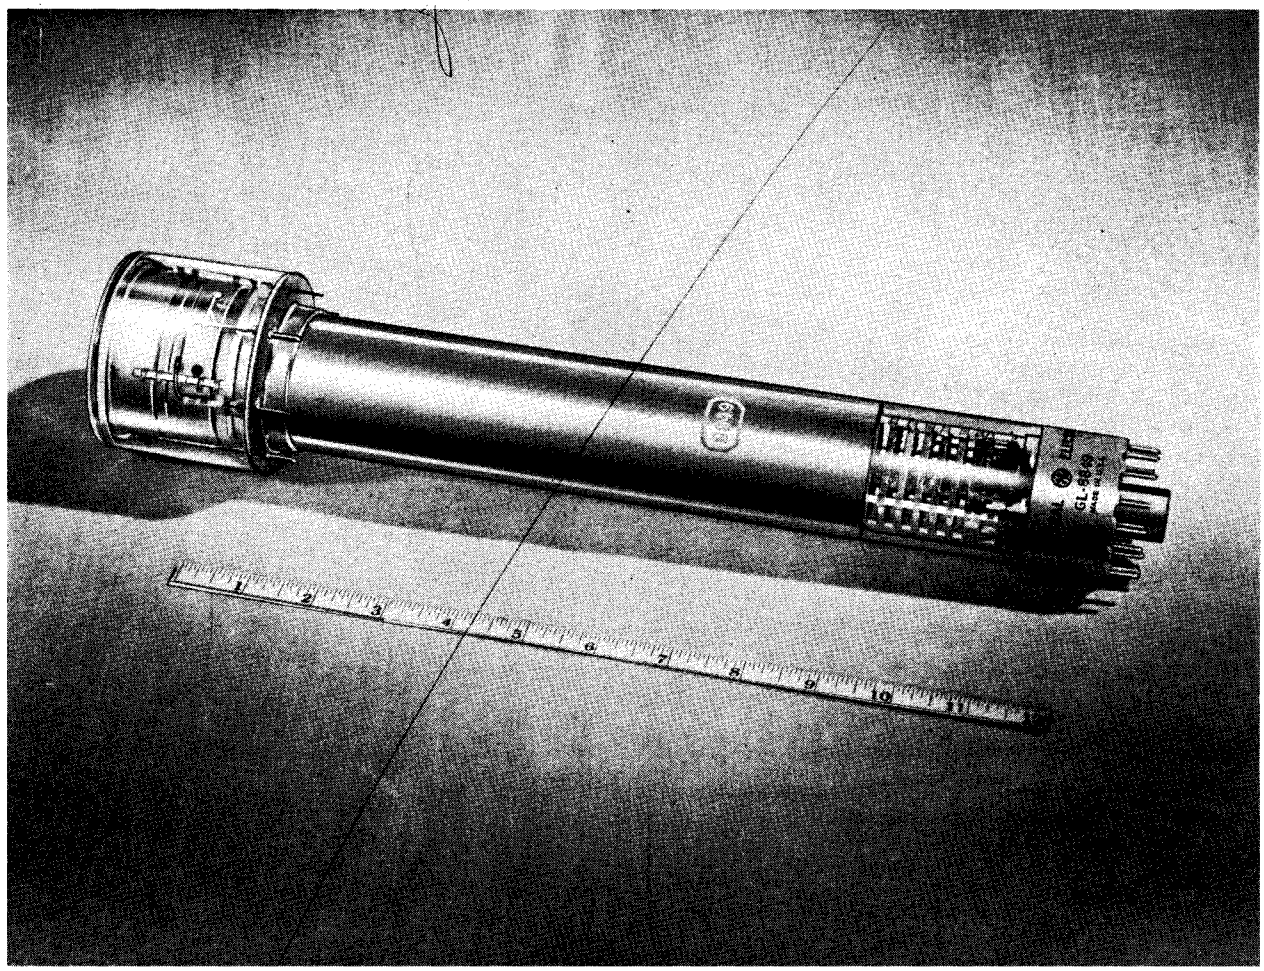

IMAGE ORTHICON

MAGNETIC FOCUS **MAGNETIC DEFLECTION**

LOW-LIGHT-LEVEL PICKUP

The GL-6849 is a television camera tube for extremely low-light-level pickup use. Typical applications are observation of fluoroscopic screens, scenes illuminated by starlight and direct images of stars.

Extremely wide target-to-mesh spacing reduces smearing or lag of moving images at low light levels by better beam modulation. This results in an increase in signal-to-noise ratio at low illumination levels. Wide spacing eliminates microphonics originating in the target-mesh assembly.

The GL-6849 photocathode is characterized by a spectral response with high blue and high green sensitivity, very good yellow sensitivity and good red sensitivity. It has practically no infra-red sensitivity. This characteristic of the response permits portrayal of colors in nearly their true tonal gradation since it prevents any color-masking by infra-red.

TETRODE

ONE KILOWATT UHF TELEVISION OUTPUT
UHF TETRODE
GROUNDED-GRID CIRCUITS
FORCED-AIR COOLED
METAL AND CERAMIC
INTEGRAL RADIATOR
THORIATED-TUNGSTEN CATHODE

The GL-6942 is a four-electrode transmitting tube featuring a metal-and-ceramic envelope designed for use as a power amplifier or oscillator in grounded-grid circuits with both grids maintained at radio-frequency ground potential. The output circuit is connected between the anode and the screen grid. The anode is capable of dissipating one and one-half kilowatts. Cooling is accomplished by forced air with the radiator an integral part of the anode. The cathode is indirectly heated thoriated tungsten. Maximum ratings apply up to 1000 megacycles.

When used as a Class B grounded-grid broadband television amplifier this tube has a useful synchronizing peak-power output of one kilowatt at 900 megacycles; in narrow band Class C service the output is one kilowatt of continuous power as an amplifier or oscillator. Because of its ratings, the tube is also well adapted to use in dielectric-heating equipment.

High operating efficiency is assured because of the small size and close spacing of the tube electrodes, the ring-seal construction, and the low-loss factor due to the silver-plated external parts and the ceramic insulators. In addition, the grounded-grid construction eliminates the necessity for neutralization in a properly designed circuit. The small size of the GL-6942 permits compact mounting, and the ring-seal construction allows quick plug-in installation.

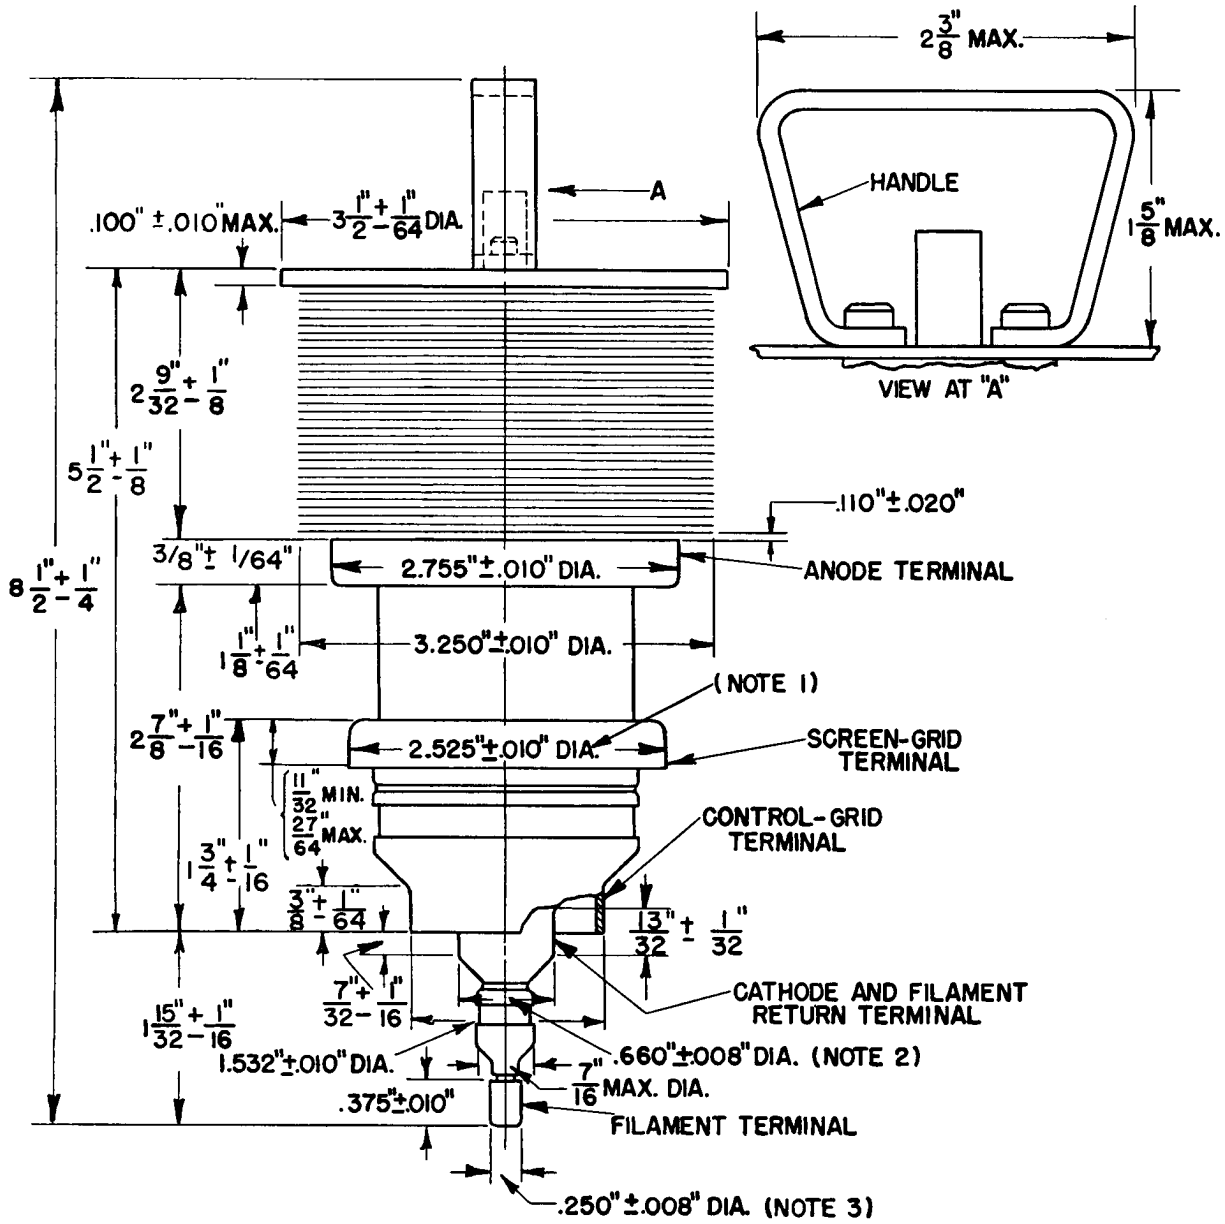
* The cathode of the GL-6942 because of transit-time effects which raise the temperature of the cathode, is subjected to considerable back bombardment in ultra-high-frequency service. The amount of heating due to bombardment is a function of the operating conditions and frequency, and must be compensated for by a reduction of the heater input to prevent overheating of the cathode with resulting short life. For long life, the GL-6942 should be put in operation with rated heater voltage. After the circuit has been adjusted for proper tube operation the heater voltage should be reduced to a value slightly above that at which circuit performance is affected. At a frequency of 900 megacycles and with typical operating conditions the heater voltage can be reduced to approximately 5.3 volts. At lower frequencies, the reduction will be less. Minor circuit readjustment may be necessary after this adjustment.



TECHNICAL INFORMATION (CONT'D)

† Represents maximum useable cathode current (plate current plus current to each grid) for any condition of operation.
‡ Measured with complete external shielding between cathode and anode.
§ Output capacitance measured between anode and screen grid. Control grid connected directly to screen grid.
¶ The volume of cooling air indicated for the various seals is for sea-level conditions and approximate only. Distribution of cooling air will vary with the cavity configuration about the tube. For most satisfactory operation the maximum temperature of any point on the tube should be below 200 C.
ϕ Useful power output including power transferred from driver stage.
⧫ The carrier of the driver modulated 100 percent.
▲Modulation essentially negative may be used if the positive peak of the envelope does not exceed 115 percent of the carrier conditions.

*To prevent mercury condensation, the anode-header temperature should be higher than the cathode temperature at all times. Mercury must be kept away from the anode and anode seals. Before tube operation, the anode seals must be warmed, with respect to the cathode, long enough to vaporize all mercury from the seal area.

†Dampened oscillations are permissible provided the dampening coefficient is less than the value shown on the current-waveform curve. The peak of the oscillation must not exceed 48,000 amperes.

‡Tube must be operated within the area specified on the current-waveform curve.

GL-7293

IMAGE ORTHICON

FIELD-MESH **MAGNETIC FOCUS AND DEFLECTION**

The GL-7293 is a television camera tube for both outdoor and studio pickup service.

The tube features a field mesh in the scanning section which minimizes landing and shading errors, prevents geometric distortion, provides sharp transition from black to white without spurious effect, and improves corner resolution.

A suppressor grid assures excellent signal-to-noise ratio by preventing field-mesh secondary electrons from entering the electron multiplier and reducing beam modulation.

A photocathode with a spectral response close to that of the eye permits portrayal of scenes in nearly their true tonal graduation.

In operation alignment is performed with the lens open on a chart or scene since dynode apertures are not visible with the lens capped.

The GL-7293 is interchangeable with the 5820. The field-mesh feature, however, results in improved performance.

GL-7390

HYDROGEN THYRATRON

40 KILOVOLTS PEAK
33 MEGAWATTS AT 60 KILOWATTS

CERAMIC ENVELOPE
EXTERNAL ELECTRODES

The GL-7390 is a hydrogen thyratron for radar modulating and other pulsing applications. It will carry high peak currents and withstands very high voltages.

Mechanically the tube features a heavy-duty ceramic envelope and external electrodes to improve heat dissipation.

The high-peak-power ratings of this tube and its mechanical design features assure reliable service under the stringent operating conditions encountered in high-power pulse equipment.

Thermal

Type of Cooling—Convection¶		
Ambient Temperature Limits	−55 to +75	C

MAXIMUM RATINGS—ABSOLUTE VALUES

Maximum Peak Anode Voltage		
Inverse▲		
Forward, ♦ minimum supply voltage = 3500 volts d-c	33,000	Volts
Maximum Cathode Current		
Peak	2000	Amperes
Average	4.0	Amperes
Maximum Averaging Time	1	Cycle
RMS‖	75	Amperes
Anode Dissipation Factor♥	30 x 10^9	
Maximum Negative Control-Grid Voltage before Conduction	650	Volts
Maximum Rate of Rise of Anode Current	10,000	Amperes per Microsecond

The above limits are interrelated and it does not necessarily follow that combinations of limits can be attained simultaneously. For further information consult the Tube Department, Schenectady 5, N. Y.

* The optimum reservoir voltage for operation at maximum tube voltage, maximum peak and average tube currents, and at a repetition corresponding to the rated operation factor is inscribed on the base of the tube and must be held within ±2.5 percent. Applications involving operation at other conditions will necessitate a redetermination of the optimum reservoir voltage.

**Stand-by operation with heater and reservoir voltages is not recommended. Where necessary, the tube should be operated at full equipment conditions for a minimum of two hours during each twelve-hour period of stand-by.

† The time interval between the point on the rising portion of the grid pulse which is 26 percent of the peak unloaded pulse amplitude, and the start of the anode-current pulse.

‡ Driver pulse measured at tube socket with thyratron-grid disconnected; amplitude = 1300 volts minimum, 2500 volts maximum above 0; time of rise = 0.35 microsecond maximum, measured from 26 percent to 70 percent of peak value; grid pulse duration = 2 microseconds minimum, measured between 70 percent of peak on rising side to 70 percent of peak on falling side; impedance of drive circuit = 10 to 25 ohms maximum.

¶ An air blast may be directed at the anode and upper portions of the tube envelope to extend performance under high-anode-dissipation-factor operation, provided envelope and anode temperatures exceed 150 C.

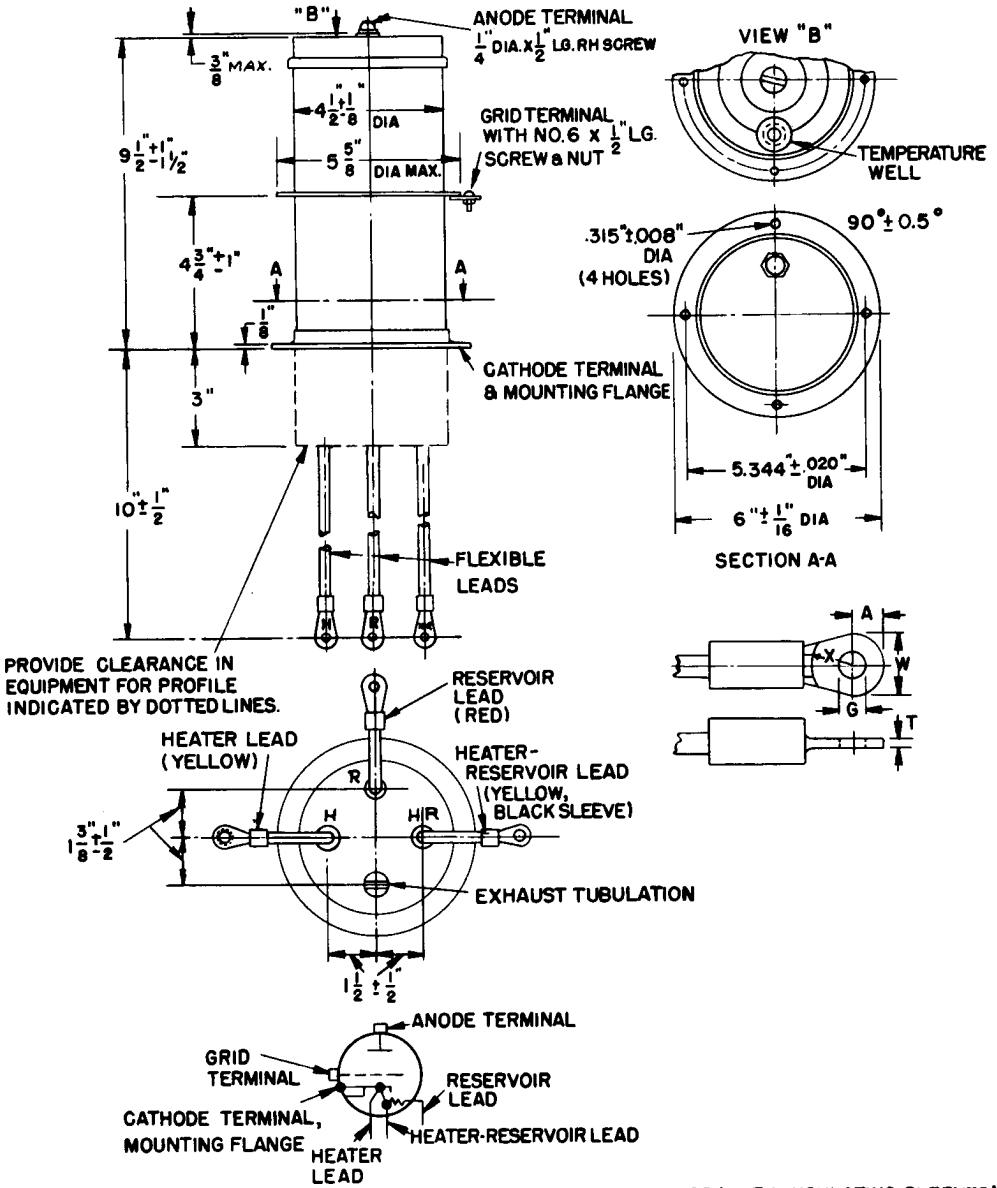
▲The minimum inverse anode voltage permissible is 5 percent of the peak forward voltage and the maximum is 5000 volts during the first 25 microseconds following the anode pulse exclusive of a spike of 0.05 microsecond maximum duration.

♦ Instantaneous starting is not recommended. However, in cases where it is necessary to apply anode voltage instantaneously, the maximum permissible forward starting voltage is 22,000 volts peak. The power-supply filter should be designed to limit the rate of application of this voltage to 550,000 volts per second.

‖ The RMS current of hydrogen thyratrons is the square root of the product of the average and peak currents.

♥Product of the peak forward anode voltage, pulse repetition rate, and peak anode current.

X-RAY WARNING NOTICE



If the GL-7390 is operated at anode voltages in excess of 16 kilovolts, X-ray radiation shielding may be necessary to protect the user against possible danger of personal injury from prolonged exposure at close range. For further information consult the following references or other standard texts on the subject:

GL-7399

TETRODE

PULSED SERVICE
GROUNDED-GRID OPERATION

FORCED-AIR COOLED
METAL AND CERAMIC

INTEGRAL RADIATOR

The GL-7399 is a small-size, four-electrode transmitting tube especially designed for pulsed-amplifier or -oscillator service at L-band frequencies. This tetrode is particularly well suited for use in airborne or ground-based radar equipment.

The tube is capable of providing useful output at frequencies up to approximately 1500 megacycles.

Features of the GL-7399 include long life and reliability, long pulse width, high peak power and high gain, broad-banding capability, and resistance to shock and vibration.

These together with such design factors as an oxide-coated cathode, coaxial elements, and metal-ceramic construction make the tube well adapted to application in modern systems where performance and reliability are important.

IMAGE ORTHICONS

FOCUS-MAGNETIC **DEFLECTION-MAGNETIC**

These low-light-level image orthicons are designed to meet a wide variety of requirements for industrial, military, and scientific applications. They provide an effective low-light-level sensitivity of 4 x 10^{-7} foot-candles photocathode illumination for resolution of 100 television lines per target-inch. The GL-7538 is designed for normal environmental operation. The 7409 is a ruggedized version especially designed to operate under severe shock and vibration conditions.

Both tubes feature a high-gain, thin-film magnesium-oxide target with a sensitivity ten to twenty times that of glass targets. The extreme thinness and the anisotropic property of this semiconductor target virtually eliminates lateral leakage and increases the resolution 25 to 50 percent over that of standard glass targets. Since operation of the target depends on electron conduction, which is not a depletion process, rather than on ion conduction, permanent stickiness and burn-in are virtually eliminated. Low gamma permits a very wide operating range.

These and other features of these image orthicons assure long life and reliable operation of the 7538 in such applications as surveillance, satellite tracking, and detection. The 7409 is particularly useful in tank fire control, drone guidance, missile-borne systems, and ground vehicle systems operating over rough terrain.

† Although these tubes will operate in standard equipment, modification to permit operation at these values will improve effective sensitivity for most applications.

‡ These values will permit the best low-light-level-sensitivity capability of the tube to be realized and will assure the maximum useful multiplier gain required in extreme low-light-level applications. The resolution sensitivity information in this data sheet was derived with these higher multiplier voltages.

§ Adjust to give the most uniformly shaded picture near maximum signal.

‖ 75 to 85 percent of photocathode voltage.

¶ The target supply voltage should be adjustable from −3 to +5 volts with blanking voltage off. Maximum target voltage is +10 volts above target cutoff. Recommended target voltage is +2 volts above cutoff. Slight readjustment, usually only a small fraction of a volt, may be necessary to minimize microphonics.

**Direction of current should be such that a north-seeking pole is attracted to the image end of the focusing coil, with the indicator located outside of and at the image end of the focusing coil.

Adjust to produce flattest field with maximum response. Alignment is correct when the center of the picture merely goes through focus and does not rotate when beam focus (Grid No. 4) is varied. For most commercial focus coils a 75-gauss field results from a focus-coil current of 75 milliamperes.

GL-7409

ENVIRONMENTAL

Shock: Per specification MIL-E-5272C (ASG) Paragraph 4.15.5 except:

A 12 impact shocks of 30g

B The shock shall be applied in the following directions:
1—Vertically perpendicular to longitudinal axis, 3 shocks in each direction.
2—Parallel to the minor horizontal axis, 3 shocks in each direction.

C The shock pulse width is defined by the use of a 0.2 to 250-cycle-per-second filter.

Vibration: (10g) Per MIL-E-5272C (ASG) Paragraph 4.7.12 Procedure XII except at operating temperature only. Center horizontal resolution at 3 x 10^{-5} maximum foot-candles, photocathode illumination will be at least 350 lines (EIA) with 5g applied acceleration in the frequency range from 50 to 500 cycles per second and a double amplitude of 0.036 inch from 5 to 50 cycles per second. Picture resolution of 350 TV lines (EIA) is defined as readable through any interference that may occur.

Humidity: Per MIL-E-5272C (ASG) Paragraph 4.4.1 Procedure 1. Following this test, the interelectrode insulation of the end pins 5, 6, 7, 8, 9, and 10 each with respect to all other end base pins grounded and with 350 volts (minimum) applied is greater than 500 ohms.

Acceleration: (70g) Constant acceleration when applied perpendicular to the longitudinal axis of the tube for 10 minutes.

OPERATING NOTES

Some magnesium-oxide targets may be damaged permanently if directly and intermittently exposed, while in operation, to extremely bright sources which cause high photoelectron densities to occur at the target. Such sources include the sun, photoflash lamps, and exploding wire flashes. Damage, if it does occur, takes the form of black image spots burned in the target by the intense light.

In most cases an 80-megohm, ¼-watt resistor in series with the photocathode in the camera will protect the tube. This resistor will not interfere with normal operation of these or other image orthicons which may be used in the modified camera.

If these or similar bright sources are to be observed continuously, appropriate exposure control of photocathode illumination can be supplied by neutral-density filters.

SPECIFIC PARAMETERS ON RECORDED DATA

All curves except spectral-sensitivity characteristics were recorded under the following conditions:

Camera Chain: General Electric TE-5 (modified)
Amplifier bandwidth—total 20 mc, flat to 6 mc

Resolution Chart: National Bureau of Standards Lens Test Chart, 100% contrast transparency.

Window Chart: 100% contrast, 1% area window for signal-noise and transfer characteristic data.

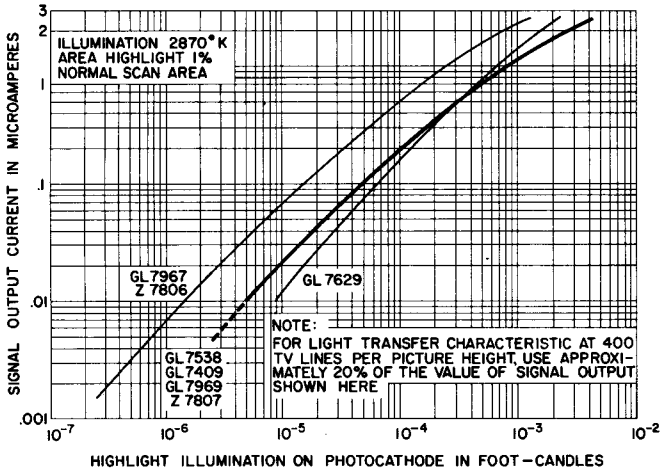
Light Source: 2870^0 Kelvin—tungsten

Light Level: Aperture and neutral density controlled (within specially constructed low-light-level box) to provide range from 10^{-8} to 10^{-2} foot-candles illumination on photocathode. For corresponding scene brightness in foot-lamberts when using Leitz f/1.5 lens (85 mm), multiply photocathode illumination in foot-candles by 12.

Operating Temperature for Image End: 25 to 30 C.

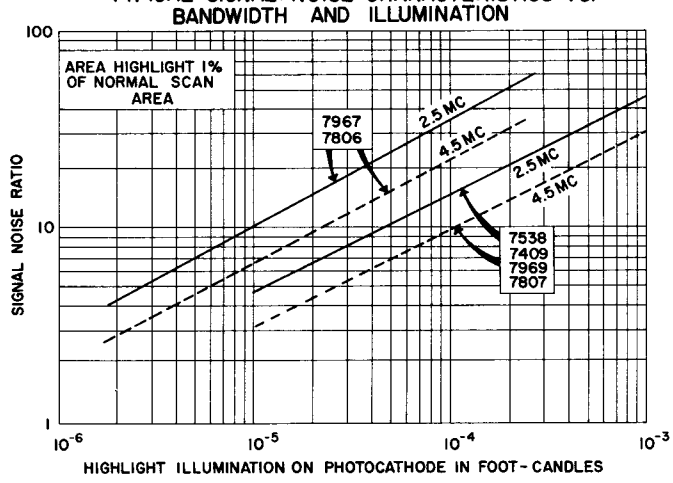
Target Raster: Target diameter is 1.40 inches. For corners of scanning raster just touching target edge raster dimensions are:

Aspect Ratio	Horizontal	Vertical
1 x 1 (square)	0.99″	0.99″
4 x 3 (standard)	1.12″	0.84″



Horizontal TV lines = 1.12 x TV lines per target inch

Vertical TV lines (EIA) = 0.84 x TV lines per target inch



Resolution sensitivity data is recorded in TV lines per target inch

Therefore, 700 TV lines per target inch = 784 horizontal lines
= 588 vertical lines (EIA)

IMAGE ORTHICON

FOCUS—MAGNETIC DEFLECTION—MAGNETIC

ENVIRONMENTALIZED

The GL-7409 is an environmentalized image orthicon designed to meet industrial and military applications where adverse environment precludes the use of standard tubes. It has an S-10 photosurface. Because of the low gamma, the tube has a very wide operating range at low light levels.

This tube features a high-gain, thin-film, magnesium-oxide target with a sensitivity ten to twenty times that of glass-target tubes such as the 5820. This target has several advantages. Its extreme thinness and anisotropic property virtually [illegible] leakage, which increases the resolution [illegible] percent over that of the standard target. It adapts the tube for service where the signal is stored for long periods before being read off, which permits additional sensitivity by use of low frame rates or by beam pulsing. It completely eliminates both stickiness and permanent burn-in since operation depends on electron conduction, which is not a depletion process, rather than on ion conduction. The curve shown on page 3 compares the resolution sensitivity of the 7409 with that of a 5820 with equivalent photocathode.

The target characteristics also assure a higher amplitude response than that of the 5820. Another advantage of the GL-7409 is a considerable reduction in the redistribution of target secondary electrons which reduces image-edging effect, particularly at [illegible] white transitions.

* Adjust to give the most uniformly shaded picture near maximum signal.

† Direction of current should be such that a north-seeking pole is attracted to the image end of the focusing coil with the indicator located outside of and at the image end of the focusing coil.

Note 1: Per specification MIL-E-5272C (ASG) Paragraph 4.15.5 with the following differences:

A) 12 impact shocks of 30 G.

B) The shock shall be applied in the following directions:

1.) Vertically perpendicular to longitudinal axis, 3 shocks in each direction.

2.) Parallel to the minor horizontal axis, 3 shocks in each direction.

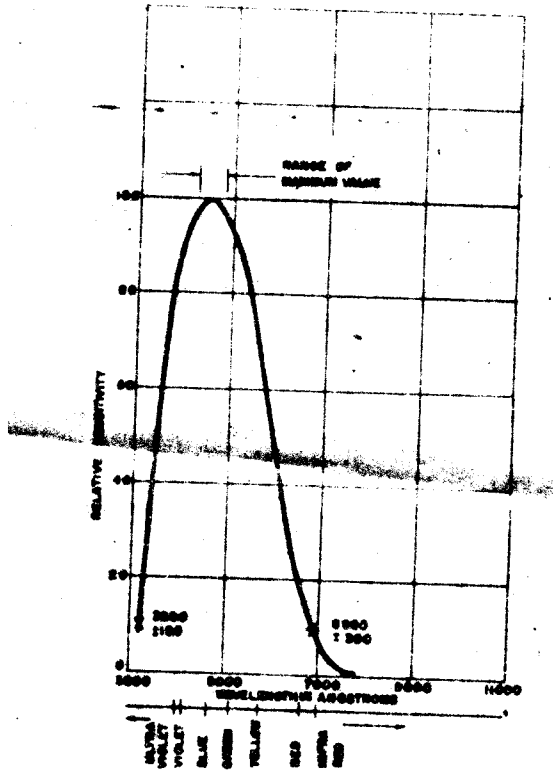
C) The shock pulse width is defined by the use of a 0.2 to 250-cycle-per-second filter.

Note 2: Under the conditions specified in MIL-E-5272C (ASG) Paragraph 4.7.12 Procedure XII except at operating temperature only. Center horizontal resolution at 3×10^{-5} maximum foot-candles, photocathode illumination will be at least 350 lines with 5 G applied acceleration in the frequency range from 50 to 500 cycles per second and a double amplitude of 0.036 inch from 5 to 50 cycles per second.

Note 3: Under the conditions specified in MIL-E-5272C (ASG) Paragraph 4.4.1 Procedure I. Following this test, the interelectrode insulation of the end pins 5, 6, 7, 8, 9 and 10 each with respect to all other end base pins grounded and with 350 volts (minimum) applied is greater than 500 ohms.

Note 4: Constant acceleration when applied perpendicular to the longitudinal axis of the tube for 10 minutes.

OPERATING NOTES



Normally a new tube will exhibit some slight after-image, characterized by a rapid and complete decay, which will gradually diminish with life. This can be minimized by use of an orbiter or by eliminating forced-air cooling for short periods of time.

Although a warm-up time of one hour is desirable, the tube can be used immediately after alignment as it cannot be damaged permanently by target burn-in.

Some tubes may exhibit microphonic bars if used immediately while relatively cool. These will disappear as the tube warms up and can be minimized during this period by slight readjustments in target voltage.

The target used in this tube greatly reduces the probability of permanent burn-in damage should a stationary highlight be imaged on the target for an extended period. However, imaging directly on the sun or other extremely bright sources should be avoided.

GL-7629
IMAGE ORTHICON

FOCUS-MAGNETIC **DEFLECTION-MAGNETIC**

The GL-7629 is a low-light-level image orthicon designed to meet a variety of applications in the industrial, military, and scientific fields. It provides an effective low-light-level sensitivity of 3 x 10^{-6} foot-candles photocathode illumination for resolution of 100 television lines per target inch, or higher where extended integration is not a requirement.

The tube features a high-gain, thin-film magnesium-oxide target with a sensitivity ten to twenty times that of glass targets. The extreme thinness and the anisotropic property of this semiconductor target virtually eliminates lateral leakage and increases the resolution 25 to 50 percent over that of standard glass targets. Since operation of the target depends on electron conduction, which is not a depletion process, rather than on ion conduction, permanent stickiness and burn-in are virtually eliminated. Low gamma provides a very wide operating range.

These and other features of the 7629 assure long life and reliable operation in such applications as low-light-level color and monochrome telecasting and closed-circuit service. The tube is also well adapted to x-ray intensifier use since it permits better detectability of lower contrasts and detail than is possible with image orthicons employing glass targets.

Field Strength of Alignment Coil, approximate#	0–3	0–3	Gausses

† Although these tubes will operate in standard equipment, modification to permit operation at these values will improve effective sensitivity for most applications.

‡ These values will permit the best low-light-level-sensitivity capability of the tube to be realized and will assure the maximum useful multiplier gain required in extreme low-light-level applications. The resolution sensitivity information in this data sheet was derived with these higher multiplier voltages.

§ Adjust to give the most uniformly shaded picture near maximum signal.

‖ 75 to 85 percent of photocathode voltage.

¶ The target supply voltage should be adjustable from −3 to +5 volts with blanking voltage off. Maximum target voltage is +10 volts above target cutoff. Recommended target voltage is +2 volts above cutoff. Slight readjustment, usually only a small fraction of a volt, may be necessary to minimize microphonics.

**Direction of current should be such that a north-seeking pole is attracted to the image end of the focusing coil, with the indicator located outside of and at the image end of the focusing coil.

Adjust to produce flattest field with maximum response. Alignment is correct when the center of the picture merely goes through focus and does not rotate when beam focus (Grid No. 4) is varied. For most commercial focus coils a 75-gauss field results from a focus-coil current of 75 milliamperes.

OPERATING NOTES

Some magnesium-oxide targets may be damaged permanently if directly and intermittently exposed, while in operation, to extremely bright sources which cause high photoelectron densities to occur at the target. Such sources include the sun, photoflash lamps, and exploding wire flashes. Damage, if it does occur, takes the form of black image spots burned in the target by the intense light.

In most cases an 80-megohm, ¼-watt resistor in series with the photocathode in the camera will protect the tube. This resistor will not interfere with normal operation of these or other image orthicons which may be used in the modified camera.

If these or similar bright sources are to be observed continuously, appropriate exposure control of photocathode illumination can be supplied by neutral-density filters.

SPECIFIC PARAMETERS ON RECORDED DATA

All curves except spectral-sensitivity characteristics were recorded under the following conditions:

Camera Chain: General Electric TE-5 (modified)
Amplifier bandwidth—total 20 mc, flat to 6 mc

Resolution Chart: National Bureau of Standards Lens Test Chart, 100% contrast transparency.

Window Chart: 100% contrast, 1% area window for signal-noise and transfer characteristic data.

Light Source: 2870^0 Kelvin—tungsten

Light Level: Aperture and neutral density controlled (within specially constructed low-light-level box) to provide range from 10^{-8} to 10^{-2} foot-candles illumination on photocathode. For corresponding scene brightness in foot-lamberts when using Leitz f/1.5 lens (85 mm), multiply photocathode illumination in foot-candles by 12.

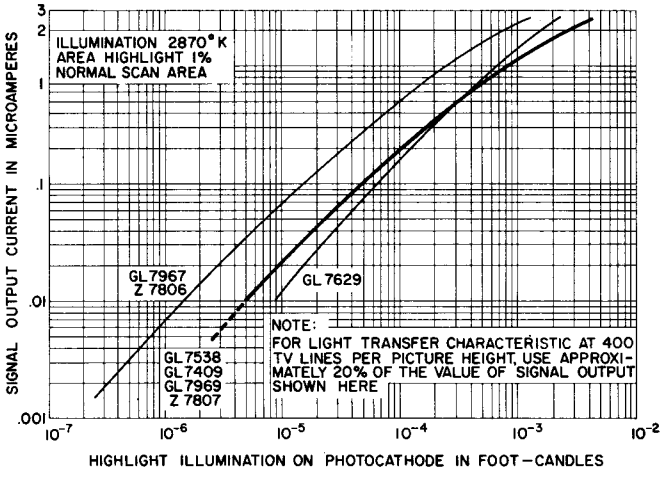
Operating Temperature for Image End: 25 to 30 C.

Target Raster: Target diameter is 1.40 inches. For corners of scanning raster just touching target edge raster dimensions are:

Aspect Ratio	Horizontal	Vertical
1 x 1 (square)	0.99″	0.99″
4 x 3 (standard)	1.12″	0.84″

Horizontal TV lines = 1.12 x TV lines per target inch

Vertical TV lines (EIA) = 0.84 x TV lines per target inch



Resolution sensitivity data is recorded in TV lines per target inch

Therefore, 700 TV lines per target inch = 784 horizontal lines
= 588 vertical lines (EIA)

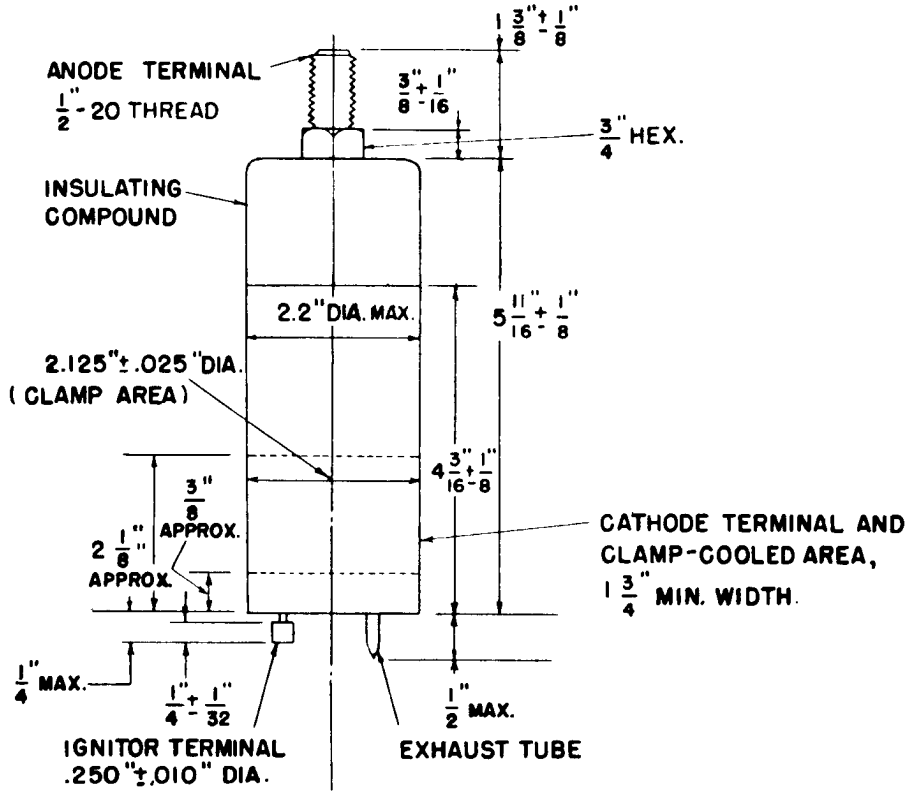
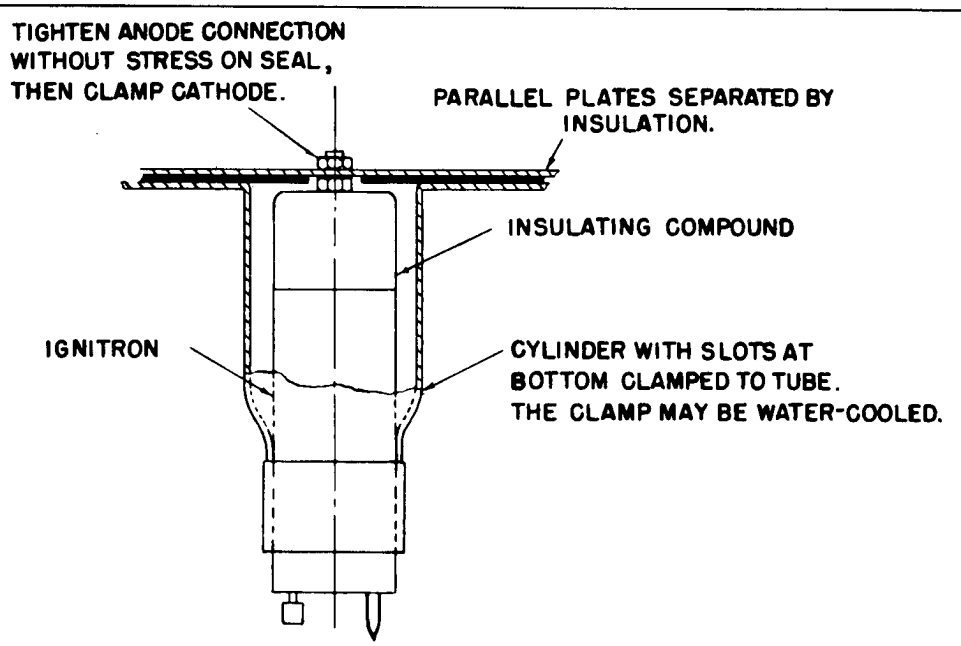
* Anode-seal, insulating-compound temperature must always be higher than the cathode temperature to prevent mercury condensation on the anode and anode seal. Before tube operation, the anode seals must be heated long enough to vaporize all mercury from the seal area.



† The tube may become a closed switch (does not open) carrying current in both directions until the current dampens out.



‡ The tube cannot hold off this voltage immediately after conduction. A 1-to-10-second delay may be required before reapplication of voltage.

¶ Dampened oscillations are permissible provided the oscillating cycles do not exceed 20. The peak current value for one-half cycle must not be exceeded.

§ Rate of rise depends on circuit.

RING-SEAL CONSTRUCTION
GROUNDED-GRID CIRCUIT

WATER COOLED
METAL AND CERAMIC
INTEGRAL WATER JACKET

The GL-7985 is a four-electrode transmitting tube featuring a metal-and-ceramic envelope for use as a power amplifier or oscillator in grounded-grid circuits with both grids maintained at radio-frequency ground potential. The output circuit is connected between the anode and the screen grid. The anode is capable of dissipating 3½ kilowatts. Cooling is accomplished by water and forced air with the water jacket an integral part of the anode. The cathode is a unipotential thoriated-tungsten cylinder, heated by electron bombardment. Maximum ratings apply up to 800 megaycles, although higher frequency operation is possible.

In narrow band, Class C, grounded-grid, amplitude-modulated service, the GL-7985 has a useful carrier-power output in excess of one kilowatt. In Class C Telegraphy, it has a useful power output of 3.0 kilowatts of continuous power as an amplifier or oscillator.

As a Class B radio-frequency power amplifier, the tube is capable of delivering 1100 watts of power with 20 watts of drive at carrier level.

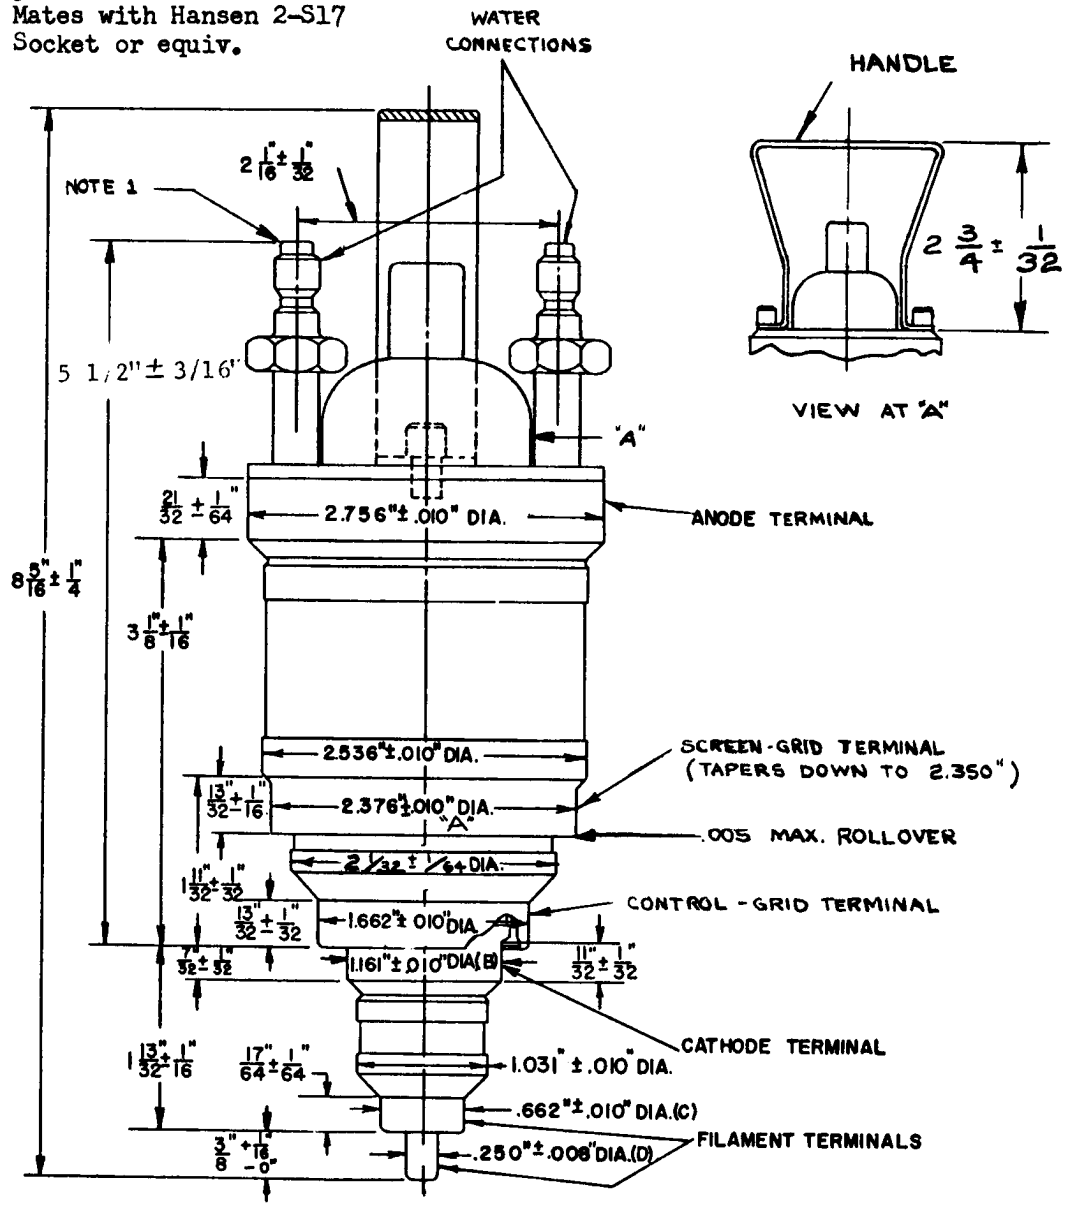
* The cathode of the GL-7985, because of transit-time effects which raise the temperature of the cathode, is subjected to considerable back bombardment in ultra-high-frequency service. The amount of heating due to bombardment is a function of the operating conditions and frequency, and must be compensated for by a reduction of the cathode power input to prevent overheating of the cathode with resulting short life. In any case it is important from a tube life standpoint to keep the cathode power at as low a level as possible consistent with required performance. Bombarder power should be monitored by a suitable wattmeter or DC voltmeter and milliammeter arrangement. For long life, the tube should be put in operation with about 180 watts bombarding power. After the circuit has been adjusted for proper tube operation, bombarding voltage should be reduced to a value slightly above that at which circuit performance is affected. Minor circuit readjustment may be necessary after the above adjustment. The procedure for determining proper bombarding power should be repeated periodically.



‡ Represents maximum usable cathode current (plate current plus current to each grid) for any condition of operation.

§ Measured with complete isolation between cathode and plate.

¶ Output capacitance measured between anode and screen grid. Control grid connected directly to screen grid.

\# Useful power output including power transferred from driver stage.

NOTE 1: Top portion same as top portion of Hansen B2T16 Mates with Hansen 2-S17 Socket or equiv.

PLIOTRON

DESCRIPTION

The GL-8002 is a three-electrode transmitting tube designed for use as a radio-frequency power amplifier at high frequencies. Multiple leads for both the filament and grid connectors minimize the inductance to these electrodes. Maximum ratings may be used up to a frequency of 150 megacycles and reduced ratings up to 300 megacycles.

DESCRIPTION

The GL-8020 is a high-vacuum rectifier that may be used at voltages as high as 40,000 volts peak inverse. This tube is particularly useful in applications which require high voltage and low current.

TECHNICAL INFORMATION

These data are for reference only. For design information refer to specifications.

GENERAL CHARACTERISTICS

Electrical

Filament—Thoriated tungsten		
Voltage	5	volts
Current	5.5–6.5	amperes
Tube voltage drop (at 100 milliamperes)	200	volts
Capacitance, plate-filament	1.4	micromicrofarads

Mechanical

TETRODE

RADIO-FREQUENCY AMPLIFIER
CW SERVICE
GROUNDED-GRID OPERATION

FORCED-AIR COOLED
METAL AND CERAMIC
INTEGRAL RADIATOR

The GL-8500 is a reliable power tetrode that delivers useful output to 1250 megacycles or higher. This tube is particularly suitable for application in the final output or driver stage of military-communications systems.

As a Class B linear amplifier in the 225–400-megacycle range, the tube will deliver 110 watts of carrier power modulated up to 100 percent. Since a power gain of 20 may be realized, drive requirements are low—approximately 5 watts at carrier level.

Operating as a Class C CW amplifier at 900 megacycles, the gain is approximately 15 at the 200-watt level.

Features of the GL-8500 include long life and reliability, high gain, high linearity, and resistance to shock and vibration.

These together with such design factors as an oxide-coated cathode, coaxial elements, and metal-ceramic construction make the tube well adapted to application in modern systems where performance and reliability are important.

* Because the temperature of the cathode is increased by back bombardment of electrons at UHF, required heater voltage for optimum life decreases with increasing frequency. The amount of heater-voltage reduction is dependent on operating conditions. However, this voltage should not be less than 5.5 volts.
† Represents maximum usable cathode current (plate current plus current to each grid) for any condition of operation.
‡ Measured with a 6-inch minimum diameter flat metal disk attached to the screen-grid ring. Control grid connected to the screen grid.
♦ Output capacitances measured between anode and screen grid. Control grid connected directly to screen grid.
§ Forced-air cooling to be applied before and during the application of any voltages.
**Provision must be made for unobstructed passage of cooling air between radiator fins and between the anode terminal and adjacent radiator fin.
♥ Useful power output as measured in output-circuit load.
¶ Useful power output including power transferred from driver stage. Output circuit efficiency approximately 80 percent.
△ Modulation essentially negative may be used if the positive peak of the envelope does not exceed 115 percent of the carrier conditions.

GL-8513

TETRODE

VHF-UHF
RING-SEAL CONSTRUCTION

GROUNDED-GRID CIRCUIT

FORCED-AIR COOLED
METAL AND CERAMIC

The GL-8513 is a four-electrode transmitting tube featuring a metal-and-ceramic envelope for use as a power amplifier or oscillator in grounded-grid circuits with both grids maintained at radio-frequency ground potential. The output circuit is connected between the anode and the screen grid. The anode is capable of dissipating 4 kilowatts. Cooling is accomplished by forced air with the radiator an integral part of the anode. The cathode is a unipotential thoriated-tungsten cylinder, heated by electron bombardment. Maximum ratings apply up to 800 megacycles, although higher frequency operation is possible.

As a Class B linear power amplifier the tube will deliver 1500 watts at carrier level.

In narrow band, Class C, grounded-grid, amplitude-modulated service, the GL-8513 has a useful carrier-power output in excess of one kilowatt. In Class C Telegraphy, it has a useful power output of 3 kilowatts of continuous power as an amplifier or oscillator.

Temperature at Any Other Point, maximum	200	C

Forced-air cooling to be applied before and during the application of any voltages. Air flow on heater-to-cathode seals must be maintained for one minute after removal of heater voltage. The radiator air ducting can be constructed so that air is forced along the anode seal and ceramic through the anode contact fingers and additional holes in the plate contact ring to accomplish the anode ceramic and anode seal cooling. The volume of cooling air indicated for the various seals is approximate only. Distribution of cooling air will vary with configuration of the cavity about the tube.

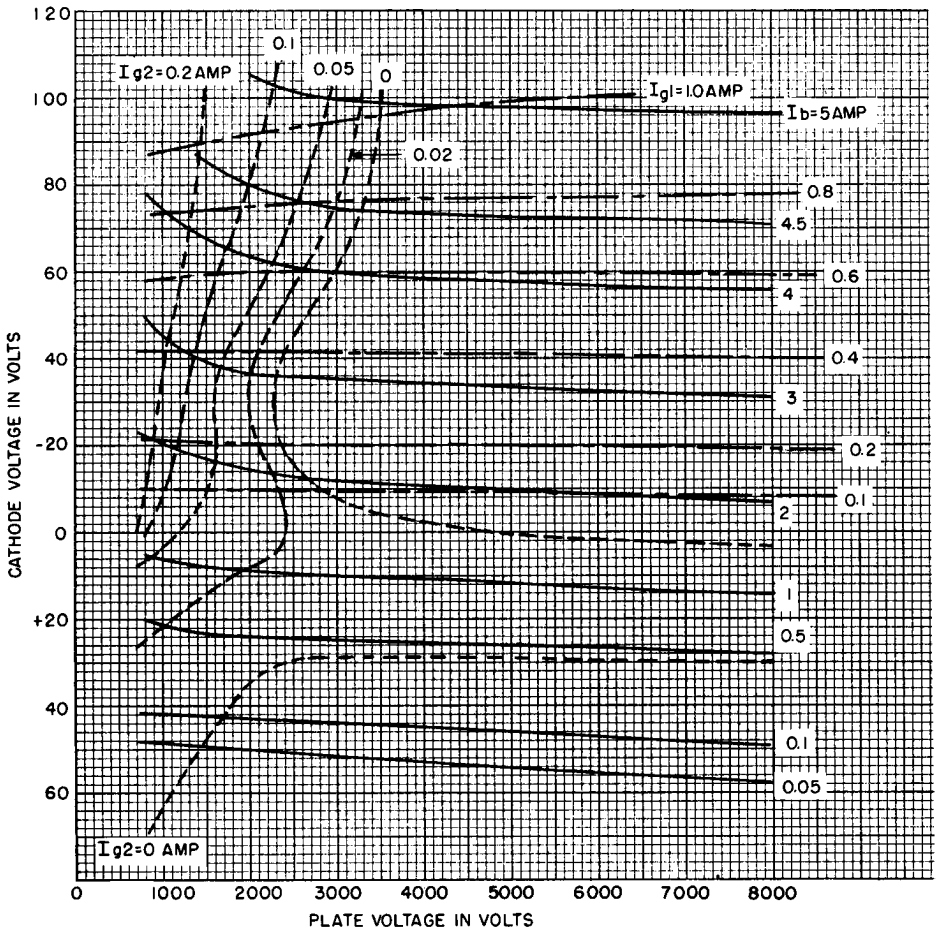
* The cathode of the GL-8513, because of transit-time effects which raise the temperature of the cathode, is subjected to considerable back bombardment in ultra-high-frequency service. The amount of heating due to bombardment is a function of the operating conditions and frequency, and must be compensated for by a reduction of the cathode power input to prevent overheating of the cathode with resulting short life. In any case it is important from a tube life standpoint to keep the cathode power at as low a level as possible consistent with required performance. Bombarder power should be monitored by a suitable wattmeter or DC voltmeter and milliammeter arrangement. For long life, the tube should be put in operation with about 180 watts bombarding power. After the circuit has been adjusted for proper tube operation, bombarding voltage should be reduced to a value slightly above that at which circuit performance is affected. Minor circuit readjustment may be necessary after the above adjustment. The procedure for determining proper bombarding power should be repeated periodically.

† Represents maximum usable cathode current (plate current plus current to each grid) for any condition of operation.



§ Measured with complete isolation between cathode and plate.

Tetrode

GL-8866

GRID-PULSED SERVICE
GROUNDED-GRID OPERATION

HEAT-SINK AND FORCED-AIR COOLED
METAL AND CERAMIC

The GL-8866 is a reduced-size heat-sink-cooled version of the GL-6283 especially designed for pulsed-amplifier or oscillator service at L-band frequencies. This tetrode is particularly well suited for use in airborne radar equipment such as IFF transponders.

The tube is capable of providing useful output at frequencies up to approximately 1500 megacycles.

Features of the 8866 include long life and reliability, long pulse width and high gain.

GL-51025

INTERNAL FEEDBACK FOR OSCILLATOR SERVICE
GROUNDED-GRID OPERATION

METAL AND CERAMIC
HEAT-SINK AND FORCED-AIR COOLED

The GL-51025 is a heat-sink-cooled triode especially designed for pulsed oscillator service in L-band. This type is particularly well suited for use in airborne or ground-based radar equipment.

The tube features internal feedback which eliminates the need for the complicated external circuit arrangements normally required in oscillator service.

Other features include small size, high peak power, long-pulse-width capability, long life and reliability.

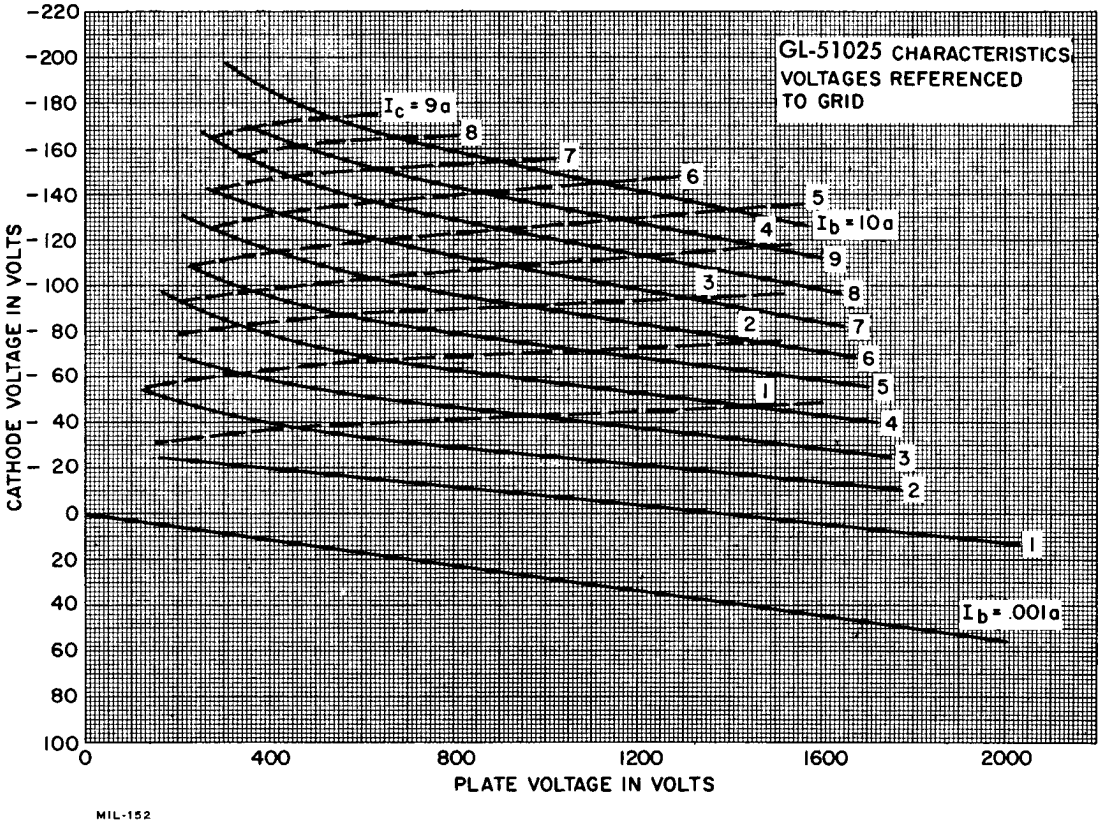
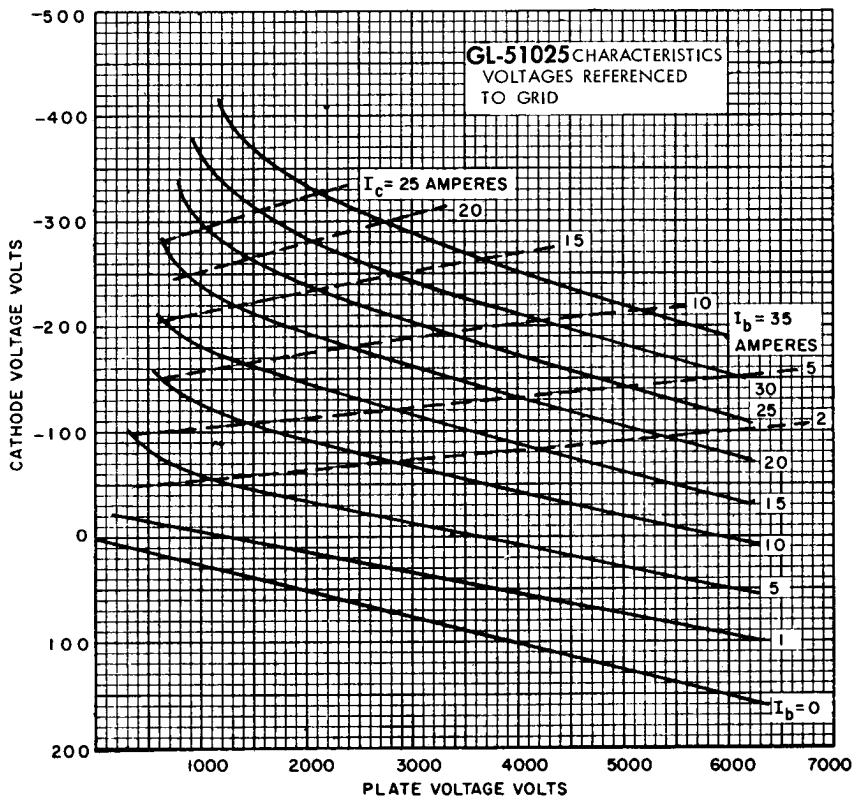
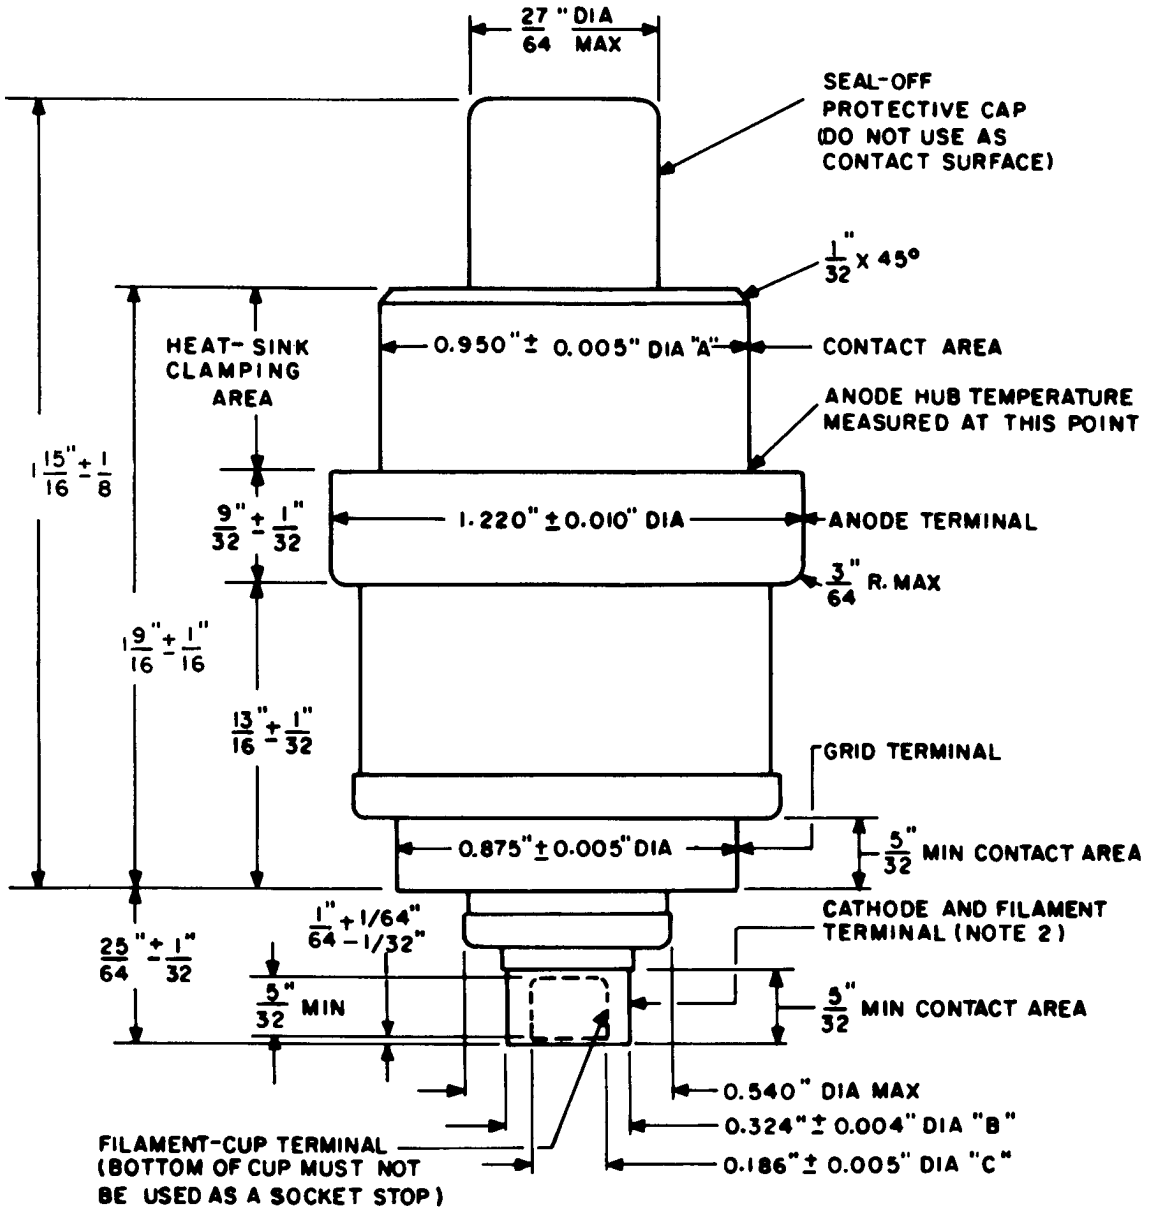
* Because of back-heating due to transit time effects, it may be necessary to reduce the heater voltage. For the 1100 mcs, 2 kw, 0.02 duty condition, the typical heater voltage is 5.5 volts. The optimum heater voltage for any application should be determined by RF performance testing.



§ A suitable clamp-on radiator or heat-sink clamping arrangement must be provided to limit the anode hub temperature to the value specified. Higher plate dissipation is allowable with provision for proper cooling.



◇ Pulse duration is measured between points at 70 percent of the peak value. The peak value is defined as the maximum value of a smooth curve through the average of the fluctuations over the top portion of the pulse. For applications requiring longer pulses, refer to the tube manufacturer.



ϕ Maximum ratio of on-time to elapsed time during any 3.3-millisecond period.

ϕϕ Maximum ratio of on-time to elapsed time during any 75-millisecond period.

** With a series grid resistance of 50 ohms.

Tetrode

GL-51038

PULSED SERVICE
GROUNDED-GRID OPERATION

FORCED-AIR COOLED
METAL AND CERAMIC

INTEGRAL RADIATOR

The GL-51038 is a small-size, four-electrode transmitting tube especially designed for RF grid-pulsed or plate-and-screen pulsed amplifier service at L-band frequencies. This tetrode is particularly well suited for use in airborne or ground-based radar equipment.

The tube is capable of providing useful output at frequencies up to approximately 1500 megacycles.

Features of the GL-51038 include long life and reliability, long pulse width, high peak power and high gain, broad-banding capability, and resistance to shock and vibration.

These together with such design factors as an oxide-coated cathode, coaxial elements, and metal-ceramic construction make the tube well adapted to application in modern systems where high performance and reliability are important.

VHF-UHF METAL CERAMIC TETRODE
4 KILOWATTS USEFUL CW OUTPUT
750 WATTS CLASS B LINEAR OUTPUT
FORCED AIR COOLED
INTEGRAL RADIATOR
THORIATED-TUNGSTEN CATHODE

The GL-51064 is a forced-air cooled power tetrode that delivers useful output to approximately 1250 megacycles. This tube is particularly suitable for application as an AM or FM power amplifier in the final output or driver stage of VHF-UHF military communications systems.

The tube features high power gain, as much as 14 db, while delivering up to 4000 watts of useful CW power as a grounded-grid Class C amplifier at 400 megacycles. An output capacitance of only 6.0 $\mu\mu$f, which is significantly low for a tube of its power handling capability, makes the GL-51064 well suited for application in equipments requiring broad electronic bandwidth.

Other features include metal-ceramic construction, a high efficiency axial flow radiator capable of dissipating 2750 watts, and an indirectly heated thoriated tungsten cathode.

LIFE PERFORMANCE

The average life expectancy of the KT66 when operated at absolute maximum ratings (see page 1) is at least 8000 hours. At a reduced absolute rating of P_{a+g2}=21W a life of at least 10000 hours should be obtained. The environment must be a static one and the valve should be switched not more than 12 times in each 24 hours. Attention should also be paid to the recommendations of the British Standard Code of Practice CP1005 *The Use of Electronic Valves.*

A valve is considered to have reached the end of life when it is either inoperative or one or more of its characteristics have reached the following values:

P_{out}	50% of initial value	
*g_m	<5·5	mA/V

*Measured at:

V_a	250	V
V_{g2}	250	V
I_a	85	mA

INSTALLATION

The valve may be mounted in any position but when horizontal it should be orientated as shown in fig. 1. No retaining device or external screening is normally necessary.

Adequate ventilation should be provided. A pair of valves working at maximum ratings should be mounted at not less than 3·5 in. (9 cm) between centres.

For the prevention of parasitic oscillation, a series resistor of 100—300Ω should be connected close to the screen tag of the valve socket. When the valve is triode connected, this resistor should be connected between screen and anode. A control grid series resistor of 10-50kΩ is also recommended. In push-pull applications having a large change in anode current between the quiescent and full output conditions, an inductance input filter circuit of good regulation should be used. A badly regulated supply will cause a fall in power output and/or excessive quiescent anode dissipation.

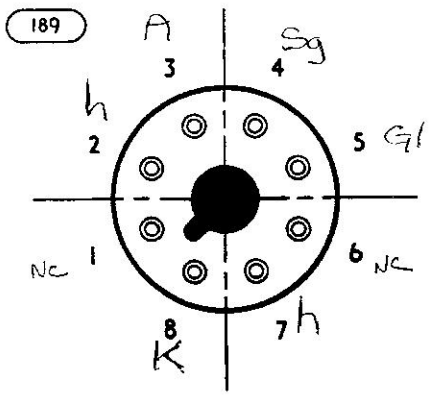

Fig. 1. Correct orientation of the valve socket for horizontally mounting the KT66.

The above curves show power output, harmonic distortion and intermodulation plotted against load impedance. Ultra-linear operation at two values of $V_{a(b)}$.

Printed in England—KC

This supplement contains comparisons of the performance of the KT66 under the three different operating conditions of triode, pentode and ultra linear connections. Design details of 30W and 50W ultra linear amplifiers are also given.

The data on normal triode or pentode operation of the KT66 is well-known and is not given here.* In ultra linear operation, the screen grid of each KT66 is returned to a tapping point on the output transformer primary. These tapping points include 20% of the total turns of each half primary, counting from the centre. The voltage during the operating cycle is not held constant, as with pentode operation, nor does it take up the instantaneous anode voltage as in the triode condition. It combines the advantages of both systems in that the high power output of the pentode is still obtainable but with the low distortion of the triode arrangement.

Considerable publicity has been given to this arrangement in the British and American press and in general the claims made are substantiated.

CIRCUIT

The circuit is shown in fig. 1. The two KT66 valves are preceded by a pair of B65 double triode valves, one of which is used as a self-balancing phase inverter and the other as a push-pull voltage amplifier. Full output is given for an input of about 150mV rms.

In ultra linear operation the KT66 valves have their screen grids returned to tapping points on each half primary. When measurements are made under triode conditions, each screen is connected to its anode, and for pentode operation, the screens are connected to the 450V line.

It has been found desirable to connect capacitors C13, C14 of 2000pF across part of the output transformer in the interests of stability. Screen grid and control grid resistors R15, R16, R17 and R18 are included for the same reason.

Independent cathode bias resistors R11, R12 of 560Ω are used, a value satisfactory for all three classes of operation.

The small capacitors C5, C6 serve to neutralise stray capacitances in the phase inverter stage and ensure that a balanced output is obtained at the higher frequencies. Their value is not critical but they should be both the same.

In order to obtain the full advantages of the ultra linear circuit, an output transformer of high quality is required. That used in the design of this amplifier was made by Partridge Transformers Ltd., Ref. No. C1732. It has two equal secondaries in order to provide either a 4Ω or 15Ω output. Other details are :—

Leakage inductance :	15mH
Primary inductance :	80H
Ratio	22:1

See the KT66 data sheet

PERFORMANCE

The curves in figs. 2 and 3 show the performance of the three classes of operation at varying anode loads. Fig. 2 shows the ultra linear circuit at three different levels of distortion compared with the triode performance at full output. Fig. 3 shows the pentode condition together with a comparative triode curve.

It will be seen that the ultra linear circuit behaves quite differently from the pentode. With the latter, full output is obtainable with a distortion which varies between 4% and 6% according to anode load. Except at the lower load impedances, the output for 1% and 2% distortion is only a small proportion of the maximum output.

In the ultra linear arrangement, almost full output is obtained at 2% distortion and very little increase is obtained if this is permitted to rise to 3%. The output for 1% distortion is about 50% of the maximum.

It will be seen that, for most values of anode load impedance, the ultra linear circuit produces only one half the distortion of the triode for equivalent outputs and is capable also of giving double the output for the same order of distortion.

The output impedance of the ultra linear circuit is considerably lower than the pentode arrangement, though higher than the triode. Measurements made at 20W output with the optimum anode load of 7kΩ show that the ultra linear and pentode circuits have impedances of 9kΩ and 35kΩ respectively. A comparable measurement on the triode circuit gave 3·5kΩ. The ultra linear circuit has, therefore, an impedance similar to the anode-anode load impedance of 7kΩ, whereas the pentode impedance is very much higher. The ultra linear circuit can exert a considerable damping factor, a valuable asset if the load is a loudspeaker.

The frequency response of the complete amplifier of fig. 1 shows a loss of 1·5db at 20c/s and 25kc/s.

OPERATING CONDITIONS

In all three classes of operation discussed, the anode and screen voltages were equal and maintained at 400 relative to the cathode. The KT66 is not normally used, as a pentode, with an equal anode and screen voltage of 400 due to the high screen current of 12mA per valve at maximum output. Under a sustained output the screen dissipation rating would be exceeded, although this method of operation is satisfactory for normal speech and music. Under these conditions, the current consumption is high but a saving is effected by the elimination of the stabiliser valve normally required in the pentode screen circuit. With the ultra linear circuit, the objection to the high current is removed since this does not exceed 7mA at maximum output. The screen current under the triode condition is, of course, lower still, at about 4mA per valve.

The data given in fig. 3 does not correspond with that previously published due to the use of a higher screen voltage. However, a closer comparison between the three operating conditions is obtained with constant voltages.

At full output, a voltage of 475 rms is present across the primary of the output transformer. The KT66 anodes therefore swing 400±340V, i.e. 60 to 740V. The two screen grids have the same d.c. potential but the a.c. voltage is one-fifth of the anode swing. They therefore operate between 335 and 465V.

COMPARISON OF OPERATING CONDITIONS

	Triode	*Pentode**	*Ultra Linear*	
$V_{a(b)}$	450	450	450	V
V_a	400	400	400	V

I_{a+g2}	125	125	125	mA
$I_{g2\ (o)}$	5	5	5	mA
$I_{a+g2\ (max\ sig)}$	135	155	145	mA
$I_{g2\ (max\ sig)}$	8	24*	15	mA
R_k (per valve)	560	560	560	Ω
V_k (app)	36	36	36	V
$p_{in\ (o)}$	50	50	50	W
$p_{in\ (max\ sig)}$	54	62	58	W
P_{out}	15	32	32	W
η	28	52	55	%
D (max sig)	2	⩾6	2	%
$R_{L(a-a)}$	6	7	7	kΩ
z_{out}	3·5	35	9	kΩ
$V_{in(g1-g1)(rms)}$	52	42	56	V
Relative P_{out} for given V_{in}	×1 0	×5 +7	×2·5 +4	db

*Suitable for intermittent operation only, due to excessive screen dissipation at full output. When continuous full output is required, use the operating condition : V_a=400, V_{g2}=300.

ADDITION OF NEGATIVE FEEDBACK

Negative feedback may be added to the circuit of fig. 1 when an improved performance is required. It is suggested that 14db feedback is adequate for all normal purposes, although this may be increased if necessary. The application of 14db feedback will reduce the output impedance, distortion and overall sensitivity by a factor of five. This will provide an amplifier having the following characteristics :

Input for full output :	600mV rms.
Output impedance :	1·8kΩ
Distortion :	0·5%
Damping factor :	4

The method is shown in fig. 4, the feedback voltage being introduced into the cathode circuit of the first valve. The bias resistor R22 (shown as R2 in fig. 1) is connected in the cathode circuit of one triode only. A further bias resistor and capacitor, R23, C23, are provided and feedback is applied across R24 from the secondary of the output transformer via R25.

Since the basic sensitivity of the amplifier is approximately 120mV for full output, a feedback voltage of about 500mV is required for 14db negative feedback. The output voltage is 21·5 for Z_o=15Ω and 11 for Z_o=4Ω ; therefore, the two resistors R24, R25 are chosen so that 500mV will exist at their junction at full output.

Assuming that R24 has a value of 22Ω, the value of R25 is given by $225\sqrt{Z_o}$ and the nearest standard values may be used. For Z_o=15 or 4Ω, resistors of 1kΩ or 470Ω are satisfactory.

A 50W ULTRA LINEAR AMPLIFIER

When the maximum output is required from a pair of KT66 valves they may be used with fixed bias in the ultra-linear circuit. The operating conditions are given below and the recommended circuit is shown in fig. 5.

Per Pair of Valves	*Quiescent*	*Max. Signal*	
$V_{a,g2}$	525	500	V
I_{a+g2}	70	160	mA
V_{g1}	−50/−65	−50/−65	V
†$R_{L(a-a)}$	—	8	kΩ
P_{out}	—	50	W
*D	—	2	%
P_{a+g2} (per valve)	18	15	W
z_{out}	—	6	kΩ
$V_{in(g1-g1)}$ (rms)	—	90	V
V_{in} (to amplifier in fig. 5)	—	2·5	V

†An output transformer having a ratio of 6 : 1 would be suitable for 105V output, 225 Ω.

*The distortion will vary from 1% to 3% with different valves. The performance is displayed graphically in figs. 7 and 8.

Circuit Notes.

The two KT66 valves are set to a similar quiescent current, which may be between 30 and 40mA, using the meter M and the meter shunts R46, R47. A negative bias voltage range of 50 to 65 is provided by the controls R53, R54. A quiescent current below 30mA will increase the distortion.

The bias voltage is derived from a U50 connected to the 600-0-600V transformer via the capacitors C42, C43. The resistors R55, R56, R57, R58, not only smooth the supply in conjunction with C44 but also reduce the voltage to the appropriate value. The resistors R52 to R58, associated with the bias supply, are generously rated to maintain a stable voltage.

R64 is adjusted, at about 90% of full output, to give equal cathode currents in the two output valves. It is capable of compensating for inequality of output from the driver stage and also for variations between the two output valves. When the two cathode currents are equal the distortion is at a minimum.

The anode supply is provided with an inductance filter L1, C31, C32. Due to the large variation in current with input signal the effective capacitance of C31, C32 has been made 80μF. The working voltage is excessive for a single electrolytic and C31, C32 are, therefore, connected in series to give a rated voltage of 900. This single section filter provides a ripple-free anode current. If a lower capacitance were used in place of C31, C32, an additional filter section would be required to reduce the ripple to a reasonable value, and the lower capacitance would be incapable of supplying the peak current required by a transient input signal.

At lower anode voltages the following results are obtainable. No circuit modifications are needed, the bias supply being a function of the anode voltage.

DC voltage	350	425	V
Quiescent current	25+25	30+30	mA
Max. signal current	55+55	65+65	mA
Power output	20	30	W
Anode to anode load	8	8	kΩ

The value of the components C40, C41, C45 and R59 will depend to some extent on the output transformer. R59 and C45 are optional and are used to suppress ringing. The most satisfactory method of selecting the value of these four components is by the use of a square wave generator, but an audio oscillator extending to, say, 50kc/s may be used to detect a peak in the supersonic region. C40 and C41 may be unnecessary with some types of transformer.

With the transformer used, the values shown gave a fall in output of 3db at 18-20kc/s with a load resistance of 15Ω.

Protection Against Bias Failure.

In common with other amplifiers which derive the bias potential from a separate supply instead of a cathode resistor, the 50W amplifier is rendered inoperative should the bias supply fail. Furthermore, the KT66 anode current would rise to an excessive value. The U50 is run at a very low anode current, a few milliamperes, and will, of course, have a long life.

A simple device which permits the amplifier to function with cathode bias in case of failure of the bias supply is shown in fig. 6. A triode, which could be one half of a B65 substituted for the L63 in the first stage, is connected in series with a relay across the 500V supply. The grid is taken to the bias supply. Normally the anode current is cut off and the relay short-circuits the resistor R60 connected in the cathode circuit of the KT66 valves. Should the bias fail, the relay will be energised, the relay contacts will open and the bias resistor R60 will allow the amplifier to function at about half maximum output.

Tetrode Connection. Push-Pull. Class AB1

The KT77 is designed primarily for use under ultra-linear conditions and this connection is recommended. However, similar performance can be obtained in the tetrode connected arrangement but the output impedance will be greatly increased. For tetrode connection the fixed screen supply must not exceed 300V.

D_{tot}	1·2	%

Class A Series Stabiliser (see fig. 1)

V_{in}	400	400	V
V_{out}	200	200	V
Load current	0 to 100	100	mA
Voltage change	1·0	0·2	V
Stabilisation	—	0·1	%
Regulation	0·5	—	%

Stabilisation is defined as $\frac{\Delta V_{out}}{V_{out}} \times 100\%$ for a change in V_{in} of $\pm 7\%$ corresponding to the usual maximum permitted mains fluctuation.

Regulation is defined as $\frac{\Delta V_{out}}{V_{out}} \times 100\%$ for a change in loading from zero load to full load current.

LIFE PERFORMANCE

The average life expectancy of the KT77 when operated at absolute maximum ratings (see page 1) is at least 5000 hours. At a reduced absolute rating of p_{a+g2}=25W a life of at least 10000 hours should be obtained. The environment must be a static one and the valve should be switched not more than 12 times in each 24 hours. Attention should also be paid to the recommendations of the British Standard Code of Practice CP1005 *The Use of Electronic Valves.*

A valve is considered to have reached the end of life when it is either inoperative or one or more of its characteristics have reached the following values:

P_{out}	50% of initial value	
*g_m	<9·3	mA/V
*Measured at:		
V_a	250	V
V_{g2}	250	V
I_a	100	mA

INSTALLATION

The valve may be mounted in any position. Free air circulation around the valve is desirable.

When a pair of valves is mounted horizontally it is recommended that the centres of the valve sockets are not less than 3½in. apart and that the keyways on the spigots of each valve are in the vertical plane.

When a pair of valves is mounted vertically it is recommended that the centres of the valve sockets are not less than 3½in. apart and that the keyways on the spigots lie along the line joining the centres.

Provision of circuit information in this publication does not imply a right to use any invention which may be involved and which is the subject of patents by whomsoever owned.

KT88
ISSUE 2
MARCH, 1959

The KT88 has an anode dissipation of 35W and is primarily designed for the output stage of an a.f. amplifier for which two valves will provide up to 100W output. Under intermittent conditions, an output of 150W is obtainable in Class B (see Circuit Supplement). It is also suitable for use as a series valve in a stabilised power supply.

INSTALLATION

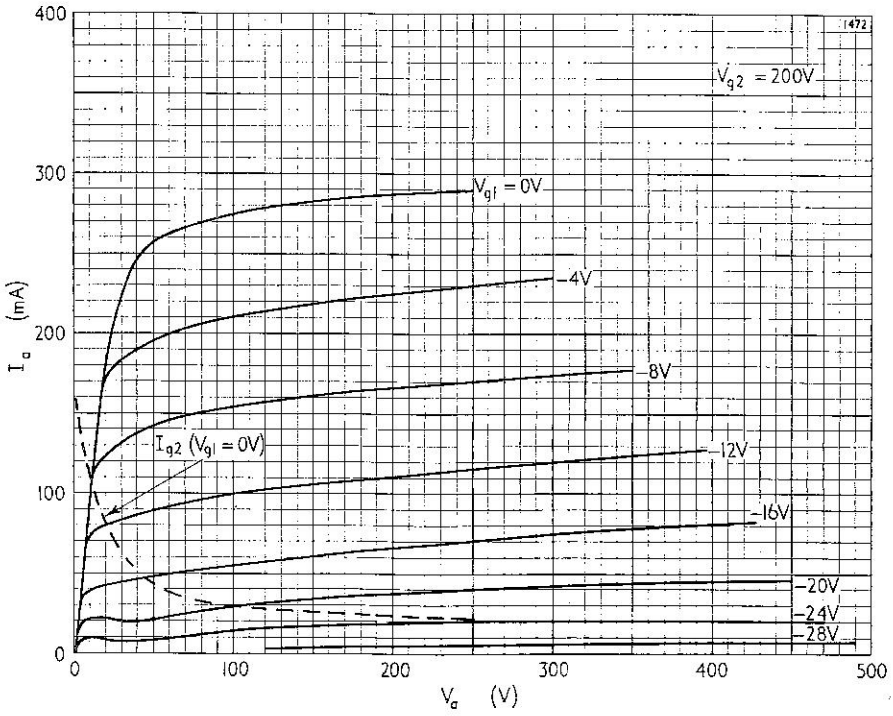
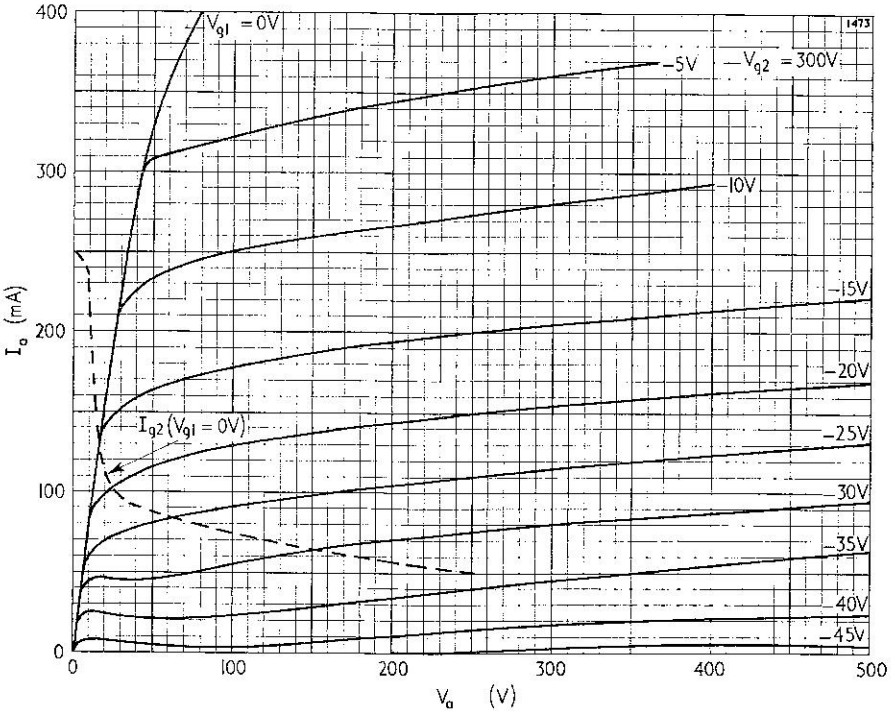
The valve may be mounted either vertically or horizontally.

When a pair of valves is mounted vertically it is recommended that the centres of the valve sockets are not less than 4in. apart and that pins 4 and 8 of each valve are in line.



When a pair of valves is mounted horizontally it is recommended that the centres of the valve sockets are not less than 4in. apart and that pins 4 and 8 of each valve are in the same vertical line.



Free air circulation around the valve is desirable.

INTRODUCTION

The KT88 may be used in pairs in either triode, pentode or ultra-linear push-pull circuits and this Supplement gives circuits and operating data for amplifiers giving outputs of 30 to 400 watts in various conditions of operation. The ultra-linear circuit is recommended for outputs up to 100W when the maximum output coupled with the lowest distortion is required and it is also used in the multiple-pair 400W amplifier described on page 20.

The curves in fig. 1 show the output and approximate distortion obtained from push-pull KT88 valves with various positions of the screen grid taps on the output transformer. At the left-hand side (0% taps) the valves are, of course, pentode-connected and on the right-hand side (100% taps) they are triode-connected. Generally speaking, the taps should be spaced at 20% to 50% of the turns on each half-primary from the centre, with 30% to 40% as the optimum. The dotted curve shows the reduction in output impedance obtained.

Either cathode bias or fixed bias may be used and the circuits show both types of operation. The former has the advantage of simplicity whereas the latter provides the normal maximum output of 100W from a pair of valves and higher efficiency.

The output power of the ultra-linear circuit is not less than that of the pentode at any given supply voltage and has the advantage that a low impedance screen supply is not required. The ultra-linear circuit does, in fact, show a rather higher efficiency in that a lower current is required from the power supply. For example, with fixed bias and a supply voltage of 460 an output of 65W is obtained with an anode current of 240mA in both the pentode and the ultra-linear arrangements but the pentode requires, in addition, a screen current of 35mA. Furthermore, it is desirable that the pentode screen supply be stabilised. The output impedance and distortion are both more favourable in the ultra-linear circuit, the former being 6·5kΩ in this example, compared with 50kΩ, and the distortion is almost entirely independent of load impedance above the rated value. Information on the effect of the positions of the screen taps upon the degree of intermodulation is given in the Appendix on page 26.

The triode connection is sometimes preferred when a moderate power output with low distortion is required. An output of up to 27W is obtainable with an h.t. supply of 485V and cathode bias and, even at lower voltages, the output is adequate for domestic amplifiers. The distortion will depend on the degree of matching between pairs but it is normal to obtain a distortion below 2% without negative feedback by the selection of two out of any three valves since this procedure, at worst, halves the normal variation in characteristics. Operating data will be found in the KT88 data sheet.

Due to the high mutual conductance of the KT88 some precautions have to be taken against parasitic oscillation whatever the circuit arrangement. Grid and screen series resistors of about 10kΩ and 270Ω respectively, are recommended. In the ultra-linear circuit, resistance-capacitance networks may be found necessary between the anode and screen taps on the output transformer as shown in fig. 4. With some transformers they will not be needed and they become less necessary as the taps include a greater part of the primary due to the consequent reduction in leakage inductance.

Details are also given for Class B operation of triode-connected KT88 valves for an output of up to 150W. This type of operation is useful when a distortion higher than that given by the ultra-linear circuit can be tolerated.

When an output exceeding 150W is needed, the KT88 valve may be used in multiple pairs in parallel push-pull instead of a single pair of larger valves. One of the advantages of this method is the low cost of the power supply which is required to give an h.t. of only 550V. Another advantage is that a valve failure in the output stage merely reduces the available output power with a probable increase in distortion.

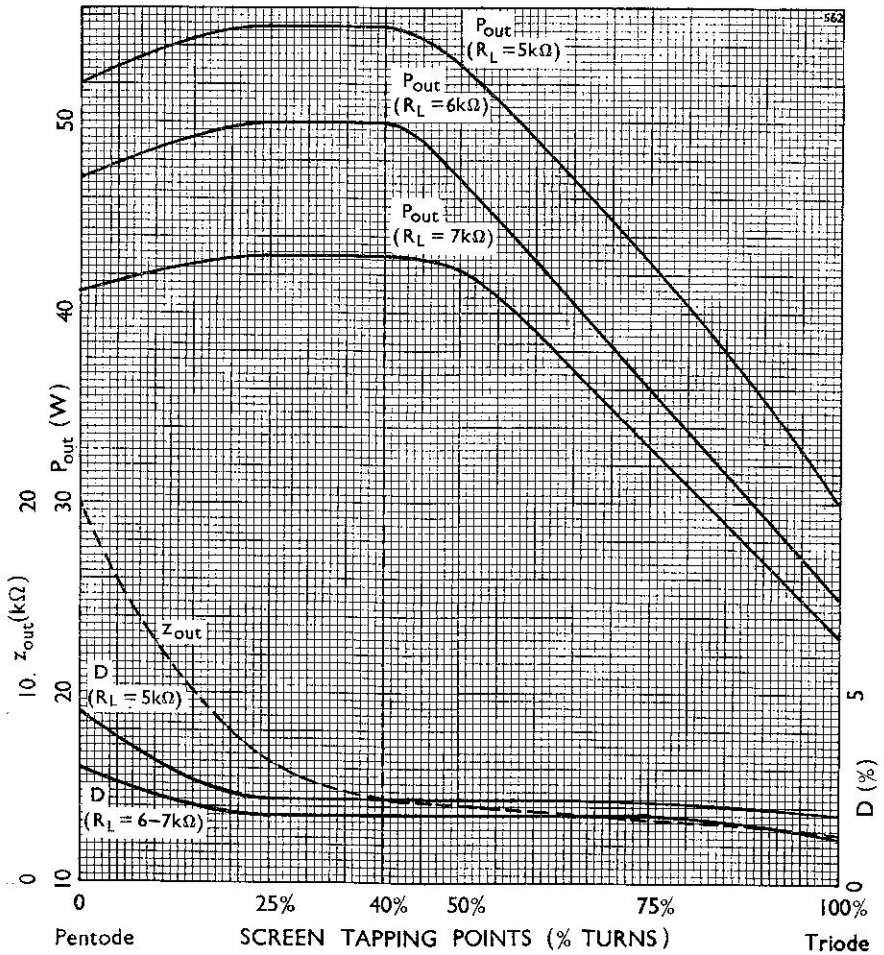

Fig. 1. Output power, distortion and output impedance of KT88 ultra-linear output stage at various positions of the screen taps from 0% to 100% of each half-primary from the centre tap.

Installation

The bulb temperature rating of 250°C must not be exceeded and any cabinet used must provide adequate ventilation. Under free air conditions this temperature is not reached at maximum ratings, but where a valve is enclosed the use of the temperature sensitive paint " Tempilaq "* is recommended to check that adequate air circulation exists.

Although the KT88 may be mounted in any desired position it is recommended that, when valves are mounted horizontally, pins 4 and 8 should be in a vertical line as in fig. 2.

When two valves are mounted vertically, in the more usual manner, on a horizontal chassis, there is a slight advantage obtained if pins 4 and 8 of both valves are mounted in line, as in fig. 3. The coolest part of the bulbs then face each other whilst the hottest parts (nearest the anodes) are at right-angles.

*Obtainable from J. M. Steel & Co. Ltd., 36, Kingsway, London, W.C.2.

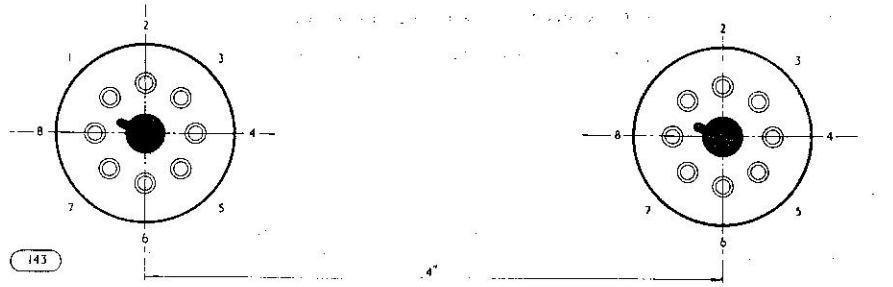

Fig. 3. Correct orientation and spacing of the valve sockets when the valves are mounted vertically.

Power Supply

The type of power supply required will depend on the operating conditions but a capacitance input filter circuit is satisfactory for the ultra-linear cathode bias amplifiers.

With fixed bias, the large change in anode current requires a low impedance power supply and an inductance input filter is essential. It is desirable for the smoothing capacitor to be of high value to prevent an instantaneous fall in voltage upon the occurrence of a transient. Satisfactory performance will be obtained with a single inductor and a capacitance of 50—150μF. Two 160μF, 450V electrolytic capacitors in series have been found very successful with the ultra-linear higher voltage working conditions.

The choice of a rectifier will depend on the power output required. The U52 or U54 are suitable for powers up to 50W, but for amplifiers designed to cover the range 50—100W, two U19 or two GXU50 rectifiers should be used.

A 30W ULTRA-LINEAR AMPLIFIER

With negative feedback, this amplifier (fig. 4) will give 32W output with about 0·25% distortion at an anode potential of 335V. The input signal to the first stage of the amplifier for full output is 500mV. Even when negative feedback is omitted the amplifier has only 1% distortion at 32W output and requires an input of 100mV. As the KT88 valves are conservatively run in this circuit they will have a long life.

Circuit Description

The output stage is preceded by a conventional double triode voltage amplifier V2 which is fed by a triode phase-splitter comprising one half of a further double triode V1. The first half of this valve is the input stage voltage amplifier, which is directly coupled to the phase-splitter. R8, in the cathode circuit of V2, reduces any signal unbalance in the phase-splitter and lowers intermodulation distortion.

Depending upon the particular characteristics of the output transformer, it may be necessary to prevent instability by connecting capacitors and resistors across part of each output transformer half-primary and " stopper " resistors in series with the grids and screens of the output stage. The curves of fig. 5 illustrate the performance of the output stage of this amplifier without feedback.

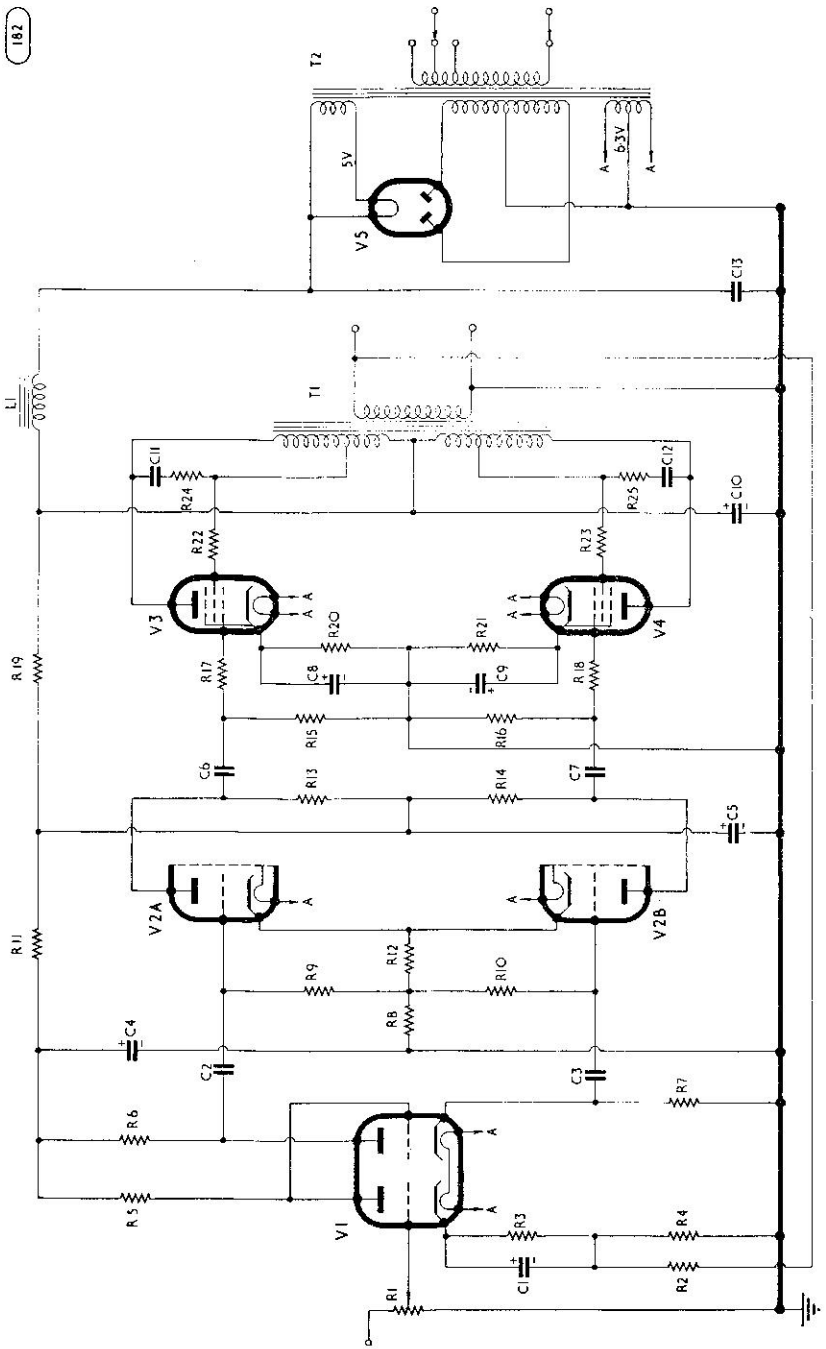

Fig. 4. Circuit diagram of the KT88 30W ultra-linear amplifier. The components list is given opposite.

The negative feedback network shown in fig. 4 provides 14db of feedback and this is adequate for all normal purposes. This value reduces the output impedance, distortion and sensitivity of the basic amplifier by a factor of 5.

Feedback from the output transformer secondary is introduced into the cathode circuit of the first stage via R2. Since the sensitivity of the amplifier without feedback is approximately 100mV, a feedback voltage of about 500mV is required for 14db feedback. As the voltage across the output transformer secondary for 32W is about 21·5 for a 15Ω load and about 11 for a load of 4Ω, the resistors R2 and R4 are chosen so that 500 mV will exist at their junction at full output. Assuming R4 to be 22Ω, R2 is given by $225\sqrt{Z_o}$ (where Z_o=the loudspeaker impedance) and the nearest standard value may be used. If Z_o=15Ω, R2 should be 1kΩ and if Z_o=4Ω, R2 should be 470Ω.

The operating conditions for the output stage of the amplifier of fig. 4 are given in Table I.

A 50W ULTRA-LINEAR AMPLIFIER

This section describes the use of the KT88 in a design for an ultra-linear amplifier with cathode bias giving 50W output at 0·2% distortion.

Circuit Description

The circuit of the complete amplifier is given in fig. 6. The design is similar to that of the 30W amplifier except for the type of input stage and the inclusion of the networks consisting of C6, R10 and C7, R11 between the first two stages. These networks reduce the amount of overshoot and consequent " ringing " in the output transformer.

The first double triode, V1, is arranged as a self-balancing floating paraphase phase nverter which feeds V2, the following push-pull voltage amplifier. Potentiometer R22 allows the signal input to the output stage to be adjusted for output stage dynamic balance.

The power supply incorporates a thermistor in the h.t. output line in order to reduce the surge from the directly heated rectifier while the remaining valves are warming up. The performance of this amplifier is illustrated in fig. 7 and the output stage operating data are given in Table II.

A 100W FIXED BIAS ULTRA-LINEAR AMPLIFIER

The circuit of this amplifier is given in fig. 8 and it provides 100W output at 5% distortion with an h.t. potential of 560V. The performance is shown graphically in fig. 9 and Table III gives the operating conditions for the output stage.

With fixed bias, the large change in anode current necessitates a low impedance power supply and, with normal rectifier circuits, an inductance-input smoothing filter is essential. The smoothing capacitor should be of high value to prevent an instantaneous fall in h.t. potential upon the occurrence of a transient signal. Satisfactory performance will be obtained with a single inductor and a capacitance of 50—150μF. The circuit diagram shows two 160μF 450V electrolytic capacitors in series as an economical method of obtaining the required capacitance.

Reducing the h.t. potential to 460V, the load impedance to 4kΩ and the grid bias to −65V results in an amplifier giving 65W output. The performance of this version is shown in fig. 10 and the appropriate operating data are included in Table III.

Protection Against Bias Failure

Should the bias supply fail, the KT88 anode currents would increase excessively and it is recommended that some device be incorporated for protecting the output valves in the event of bias failure. The arrangement illustrated in fig. 11 inserts a suitable resistor into the output stage cathode circuit which will enable the amplifier to function temporarily at half maximum output.

A triode, which could be one half of a double triode used also in the first stage of the amplifier, is connected in series with a relay across the main h.t. supply. The relay contacts are normally closed and short-circuit the emergency cathode resistor R1. The triode is held at cut-off by the connection of its grid to the bias supply at a point about 50V negative to earth. Should the bias fail, the grid of the triode will rise to earth potential and current will flow through the triode. This energises the relay, the contacts of which will open and bring into circuit the cathode bias resistor.

A 150W CLASS B AMPLIFIER

Two KT88 valves, triode-connected in Class B, may be used when maximum output for intermittent (ICAS*) operation is required. It is permissible to use a higher anode voltage than is usual, and an output up to 150W is obtained.

This type of operation is satisfactory when a distortion higher than that obtained with the ultra-linear circuit, may be tolerated. (A typical use would be in a speech modulator for a transmitter).

Circuit Description

The circuit is shown in fig. 12. In this circuit, the screen and control grids are connected via resistors R18 and R19 forming, in effect, a high impedance triode. Both grids are driven into the positive region from a driver stage capable of providing 180+ 180V r.m.s., the current drawn by the control grids being limited by R18 and R 19.

Successful operation is almost entirely dependent upon the design of the driver stage. This should have a low impedance, so as to ensure minimum distortion in the output stage.

Satisfactory results can be obtained by using a resistance loaded pentode stage. The load resistors R16 and R17 in fig. 12 also serve to reduce the 750V line to 450V for the pentode anodes. This method of supply prevents the line voltage from rising excessively during the quiescent periods, when the output stage passes no more than 15-20mA.

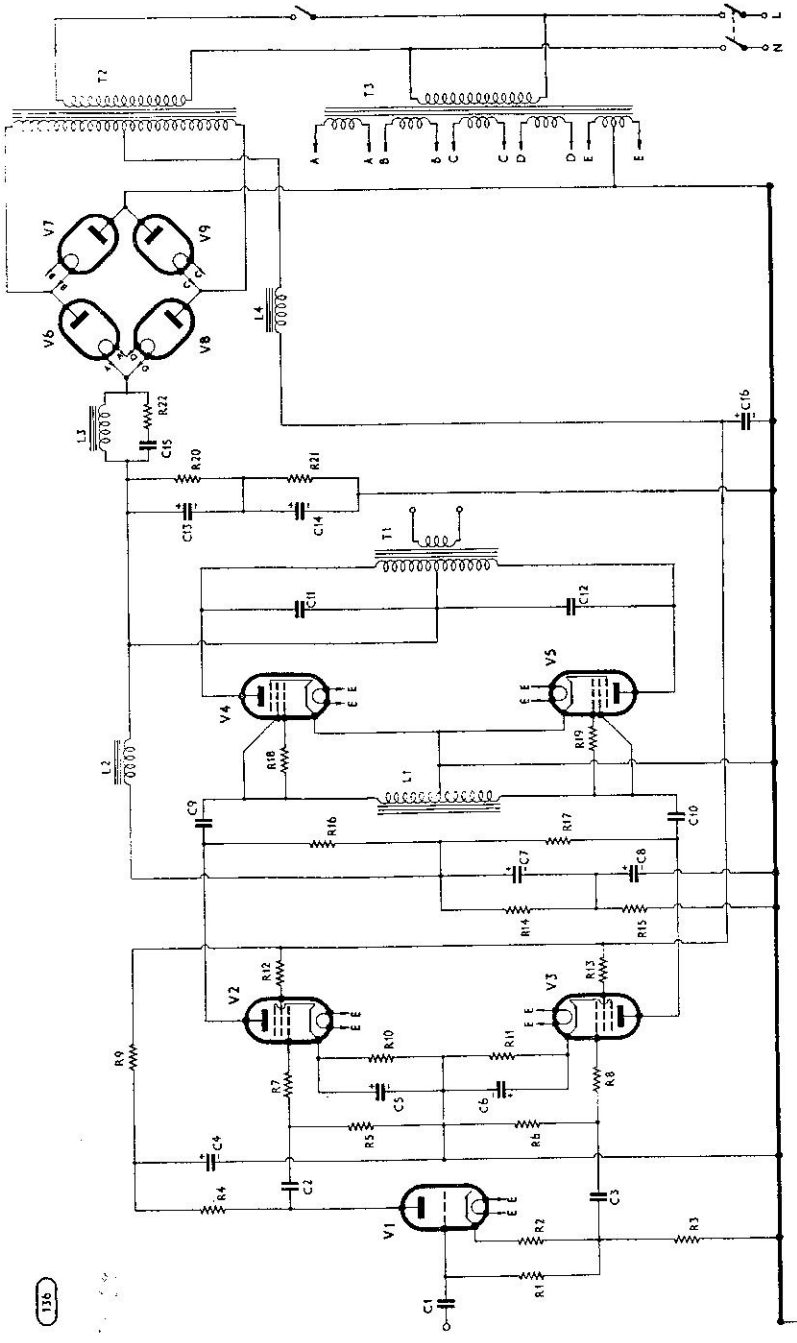

Fig. 12. Circuit diagram of the 150W Class B amplifier.

An inductance L1 is used in place of grid return resistors as the output stage grids draw some 30mA at full output. The characteristics of L1 are not critical. It should have a d.c. resistance not exceeding 500Ω, an inductance of about 20H and a centre tap. A small output transformer, with the secondary left unused, is satisfactory.

A bridge-connected rectifier system fed by a transformer giving 900V r.m.s. provides the anode supply to both the output and driver stages. A centre tap on this transformer enables half the d.c. anode voltage to be obtained for the driver screens and the previous stage(s). The electrolytic capacitors C13, C14 and C16 are of high value in order to absorb the large fluctuations of anode current (from about 120 to 400mA). The series connection of C13 and C14 permits a voltage up to 900. Suitable rectifiers are : GU50, GXU50, U52 or U54.

Table IV gives the operating conditions for the amplifier and fig. 13 illustrates its performance.

TABLE IV

CLASS B 150W AMPLIFIER
ICAS RATING

Operating Conditions

(Fig. 12)

Output Stage		
$V_{a(o)}$	850	V
$V_{a(max\ sig)}$	750	V
$V_{g2(rms)}$	60	V
$I_{a(o)}$	2×10	mA
$I_{a(max\ sig)}$	2×140	mA
I_{g1+g2}	30	mA
P_{out}	150	W
$R_{L(a-a)}$	6	kΩ
z_{out}	25	kΩ
D	6 to 8	%
p_{dr} (approx)	7	W
$V_{in(g-g)(rms)}$	360	V
z_{in}	18	kΩ
Driver Stage		
$V_{a(o)}$	500	V
$V_{a(max\ sig)}$	400	V
$V_{g2(o)}$	375	V
$V_{g2(max\ sig)}$	325	V
$I_{a(o)}$	2×50	mA
$I_{a(max\ sig)}$	2×55	mA
$I_{g2(o)}$	2×2	mA
$I_{g2(max\ sig)}$	2×7	mA
$V_{in(g-g)(rms)}$	40	V

The above conditions are suitable for normal speech applications only. For other purposes, $R_{L(a-a)}$ should be increased to 7·5kΩ. At V_a=600V an output of approximately 100W is given.

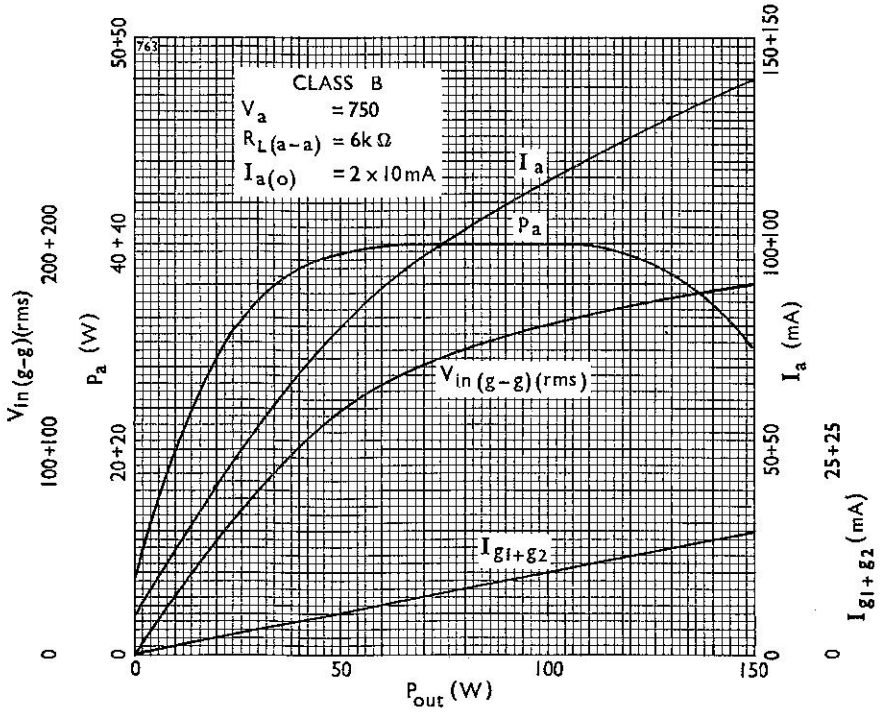

Fig. 13. Performance of the 150W Class B amplifier of fig. 12.

MULTIPLE-PAIR PUSH-PULL AMPLIFIERS

The circuit diagram of fig. 14 illustrates the use of ten valves in a fixed bias ultra-linear output stage and this arrangement gives 400W output. More or less than five pairs of valves can be used, depending upon the output power required.

A single control is used for grid bias adjustment and this simplifies the amplifier at the expense of somewhat higher distortion and lower output.

Grid Bias
550V

It is not essential to use accurately matched valves but the total current in each half of the push-pull stage should be equalised as closely as possible. This becomes easier with an increasing number of pairs and is facilitated by the cathode current meter built into the amplifier. The individual cathode currents will vary from about 35mA to about 60mA and each valve should be measured in turn and the valves sorted into two groups of approximately similar total current.

When the valves have been sorted and the two groups plugged into their respective halves of the amplifier, the optimum operating condition is obtained by adjusting the grid bias with R5 (fig. 15) so that the current drawn by any single valve does not exceed 60 mA. In this way an output of 400W will be obtained at a distortion of about 5%.

When using six or more valves in this type of amplifier, the value of the grid return resistors R14 and R15 is of importance and a low value is desirable. In order to facilitate the production of the necessary distortion-free input signal of 55+55V r.m.s., the output stage is driven by a pair of cathode followers V2B and V3B. With four output valves the grid resistors could be increased to 100 kΩ and the cathode followers dispensed with. However, as they form parts of double triodes. the saving in cost is insignificant and, on the whole, it is preferable to retain them.

The method of measuring the cathode current of each KT88 valve is shown in fig. 14. A resistor of 10Ω is inserted in the cathode lead of each valve (i.e. R38, R39, etc.) and a meter M1 is connected across this resistor through switch S1 and a series resistor (R48, R49, etc.).

It was found convenient to use a meter with a full-scale deflection of 200μA, the value of the series resistor being such that the meter indicated 0-200mA. At full output each cathode current is about 100mA to 125mA. It may be preferred to substitute the individual cathode series resistors with a single resistor inserted between the meter and switch but the possibility of instability should be borne in mind as the individual resistors act as cathode circuit isolators.

The ultra-linear output transformer must have low leakage inductance between : primary and secondary ; half-primary and half-primary ; and each half-primary and its tap. The absolute values of leakage inductance will depend upon the number of valves used but a 400W transformer used in the prototype had the following characteristics :

Primary Inductance :	4H
Leakage Inductances :	
Primary to secondary :	0·75mH
Half-primary to half-primary :	0·75mH
Each half-primary to tap :	1·5mH

To prevent ultrasonic oscillation, resistor/capacitor combinations are connected between each tap and the anode terminal of each half-primary. In the prototype, C10 and R60 were also found to be desirable, the values used being 3500pF and 1kΩ respectively.

Negative feedback may be added to this amplifier in the normal way, from the secondary of the output transformer to the cathode circuit of the input valve. The values of the resistors R2 and R3 in fig. 14 are determined by the amount of feedback and the ratio of the transformer.

Fig. 16 illustrates a recommended layout for the output valves and is self-explanatory. Adequate ventilation should be provided ; if in doubt, temperature sensitive paint should be used. (*See page 2*).

Power Supply

The design of the power supply is an important factor in the satisfactory operation of an amplifier of this type. The regulation should be good ; better than 10% with a current variation of 400-1200mA was obtained in the prototype. This order of regulation was achieved by using the xenon filled rectifier GXU1 which, in this application, is considerably under-run at a PIV of 1kV as against the rated PIV of 10kV. For up to six output valves, the smaller xenon rectifier GXU50 is suitable.

The circuit of a complete power supply is given in fig. 15 and this provides the lower h.t. voltage required by the earlier stages as well as the grid bias supply.

A single inductance-input filter is shown and, with a smoothing capacitance of 150-200μF (obtained by series-connecting two larger capacitors), this should be satisfactory for most purposes. A further filter section may be inserted if desired. The smoothing inductor(s) should have a value of 2-3H and a d.c. resistance of about 25Ω.

$V_{in(rms)}$ to first stage	250	mV

If 10db of negative feedback is applied, the last three values become 400Ω, 2% and 750mV respectively.

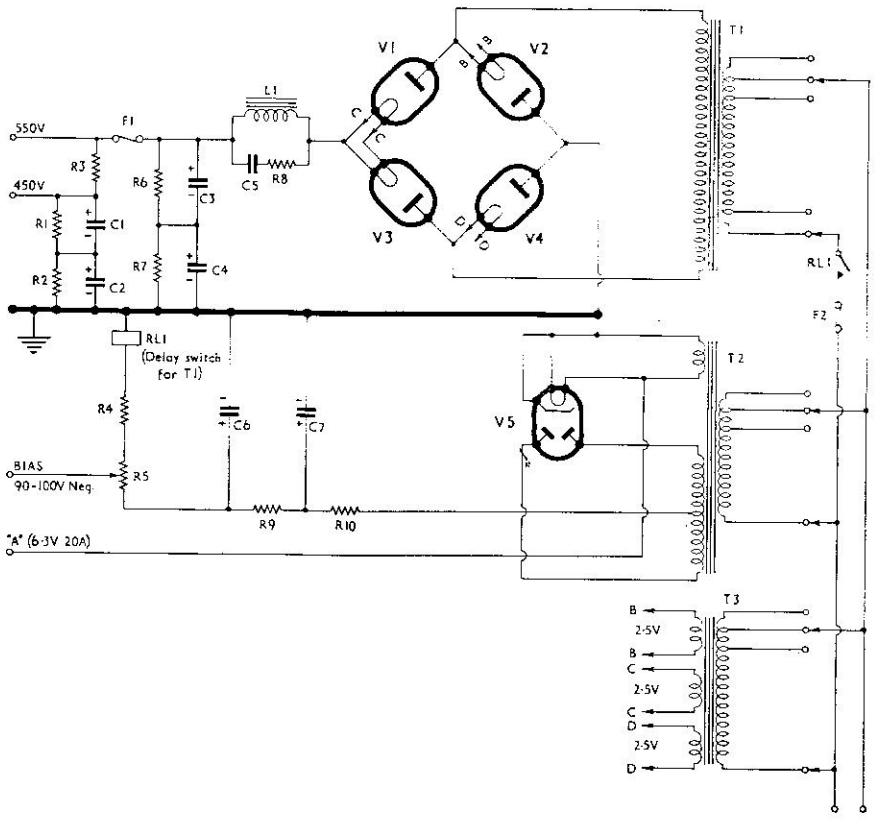

Fig. 15. Power supply circuit for the 400W multiple-pair amplifier. The winding of T3 is simplified if four identical secondaries are used. To prevent mains-borne interference with nearby receivers, generated by the xenon rectifiers, a pair of capacitors (0·05μF, 700V a.c.) should be connected in series across the 700V winding and their junction connected to the negative (earth) line.

APPENDIX

INTERMODULATION IN ULTRA-LINEAR AMPLIFIERS

The curves below illustrate the various degrees of intermodulation with varying positions of the screen taps on the output transformer from 0% (pentode operation) to 100% (triode operation). The measurements were made under SMPE conditions using frequencies of 50 and 6000 c/s at a ratio of 4 : 1. It will be noticed that the lowest level of intermodulation is obtained with taps of about 40%. A slight increase in intermodulation is produced at 33% or 57% and a significant increase at 25% or 75%.

The triode performance (100%) is inferior to the ultra-linear at all outputs except below 10W with 25% taps. The high intermodulation of the pentode arrangement (0%) is to be expected.

The application of negative feedback will reduce intermodulation roughly in proportion to the reduction in gain. For example, a 3 : 1 reduction in intermodulation is obtained with 10db and a 5 : 1 reduction with 14 db feedback. It can be seen from fig. 17 that it is not difficult to reduce intermodulation to below 1% at 50W output.

Design-Maximum ratings are limiting values of operating and environmental conditions applicable to a bogey electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making allowance for the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration.

The equipment manufacturer should design so that initially and throughout life no design-maximum value for the intended service is exceeded with a bogey tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions; and variations in the characteristics of all other electron devices in the equipment.

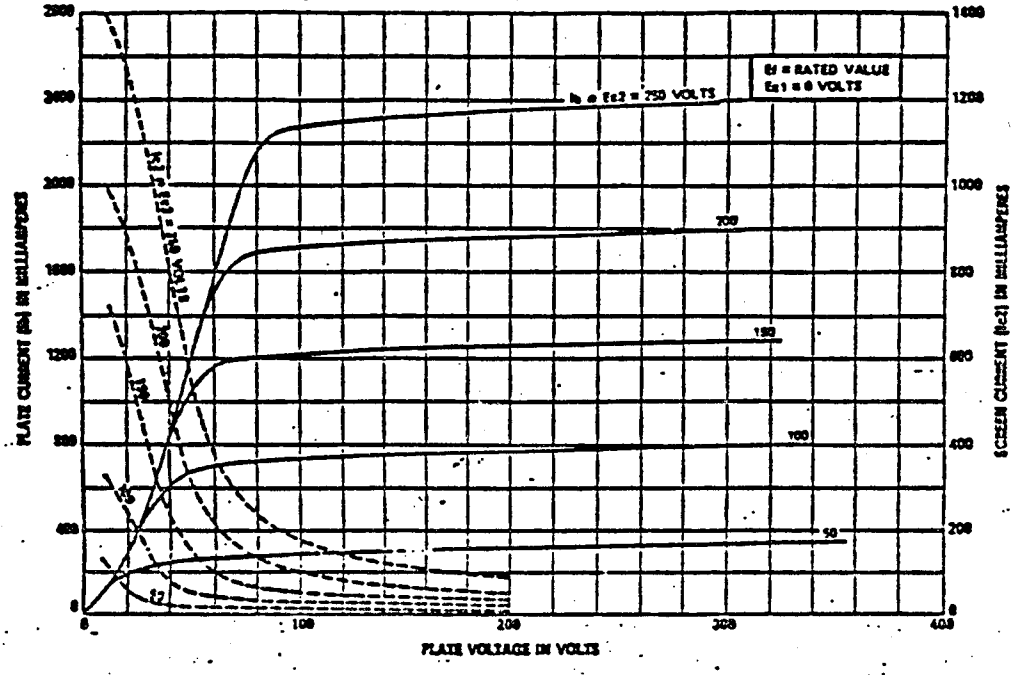
NOTES



- The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.
- Heater current of a bogey tube at Ef 13.0 volts.
- ▲ The type of input-coupling network used should not introduce too much resistance in the grid-number 1 circuit. Transformer or impedance coupling devices are recommended.
- ♦ Measured with an infrared thermometer, Ircon Model 700 BC or equivalent, at an ambient temperature of 40° C.
- § Values measured by a method involving a recurrent waveform such that the plate and screen dissipation will be kept within ratings in order to prevent damage to the tube.
- ● Triode connection (screen tied to plate) with Eb = Ec2 = 250 volts, and Ec1 = −56 volts.
- □ To be determined.

The tubes and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of tubes by General Electric Company conveys any license under patent claims covering combinations of tubes with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of the tubes with other devices or elements by any purchaser of tubes or others.

GRID RESISTOR

The maximum permissible D.C. resistance between control grid and cathode is limited to 0·27 MΩ ± 20% with auto-bias, and 0·1 MΩ with fixed bias.

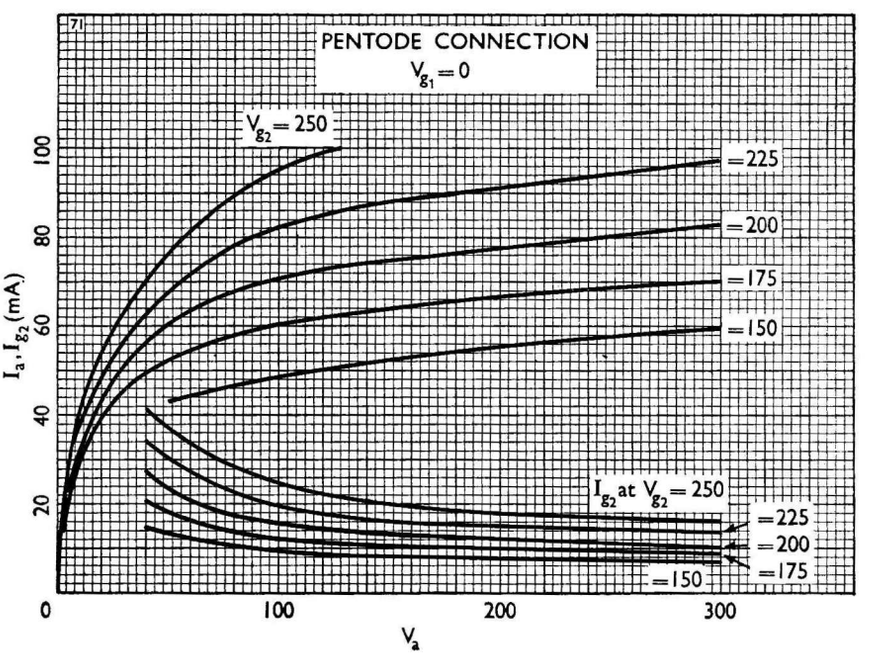
SCREENING

No internal or external screening is fitted to the valve.

MOUNTING

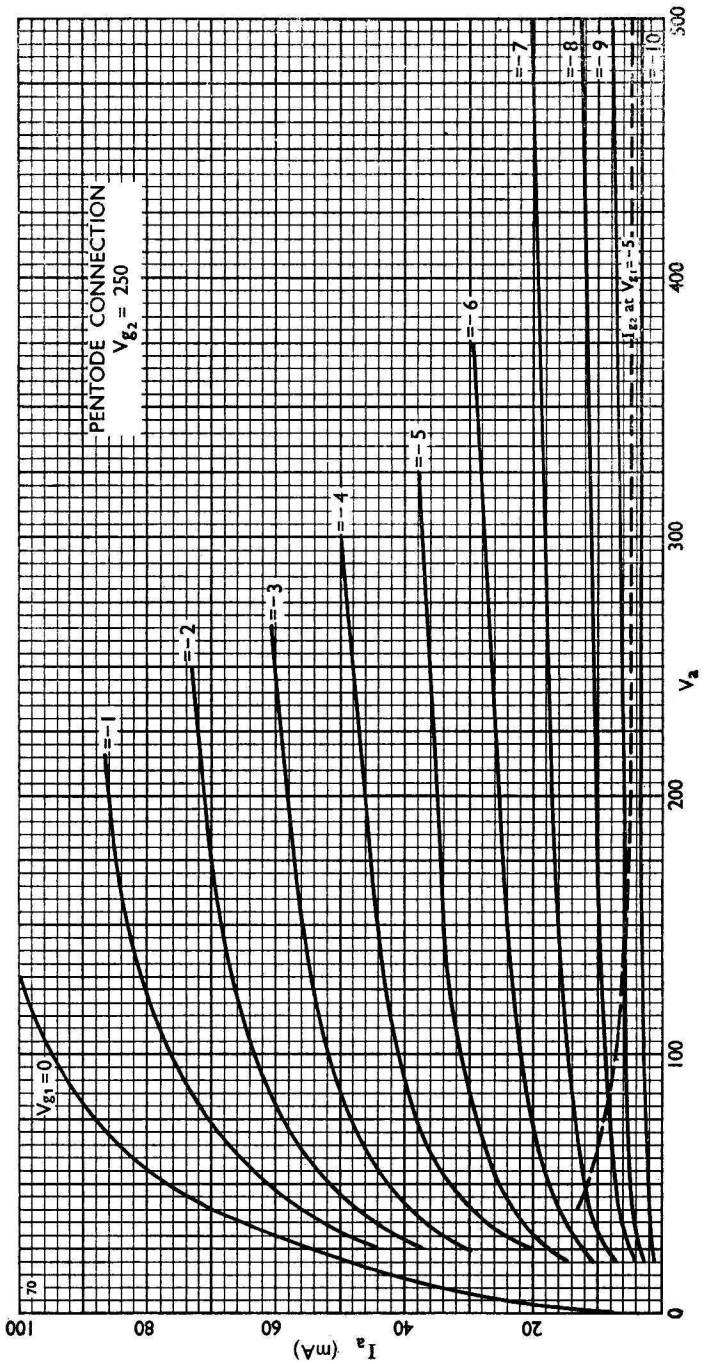
Any position.

RETAINING

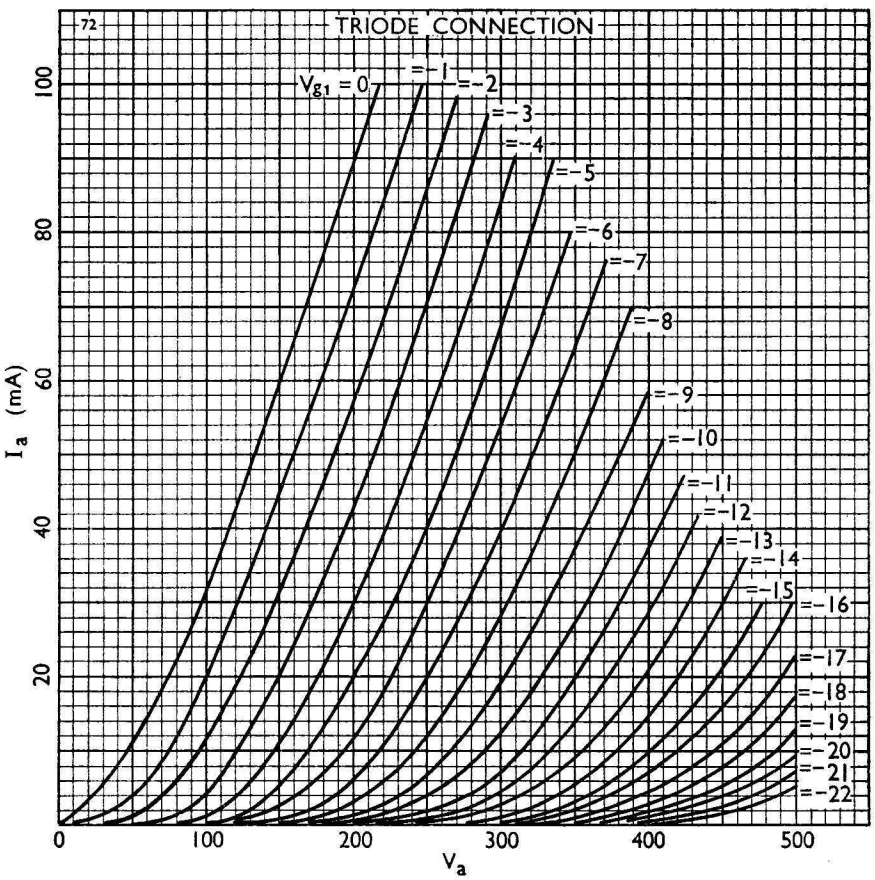


A retaining device should be used.

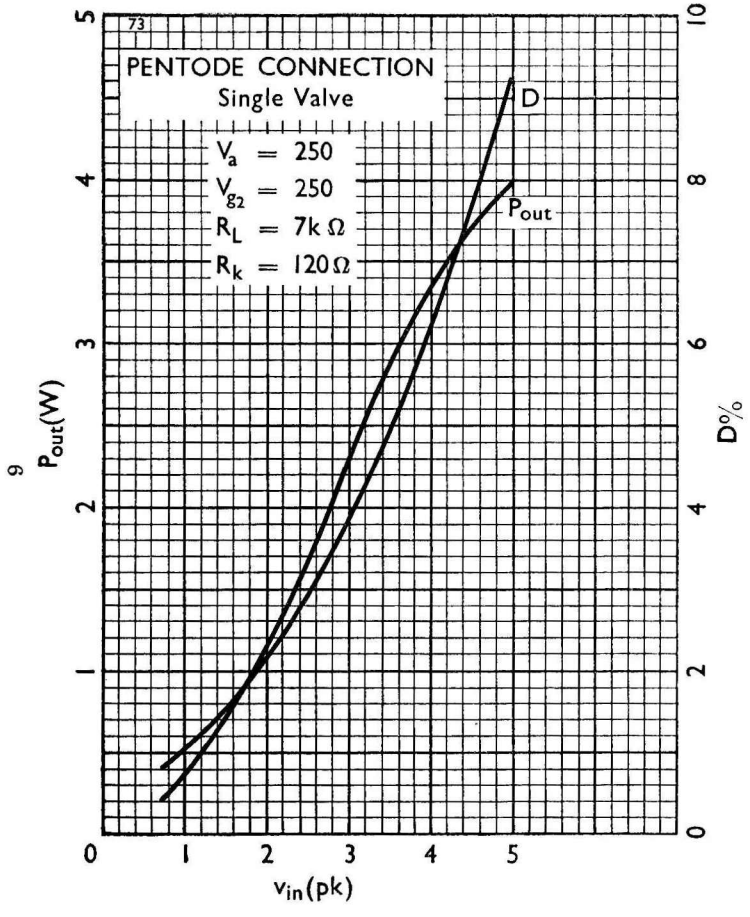
VENTILATION



Free air circulation round the bulb is preferable. If a retaining device in the form of a canister is used, the surfaces should be blackened. The temperature of the hottest part of the bulb must not exceed 250°C.



MICROPHONY



Although this is of a very low order, equipment should be designed to minimise microphony.

PHOTOTUBE

DESCRIPTION

This two-electrode vacuum phototube is designed for use in photoelectric apparatus requiring reliable and accurate control. Although it will pass some current in the visible region, the PJ-22 is designed primarily for use in the red and infrared region of the spectrum. The tube is especially useful where a high degree of stability of characteristic is required and where it is desirable to have the output directly proportional to the light flux incident on the cathode.

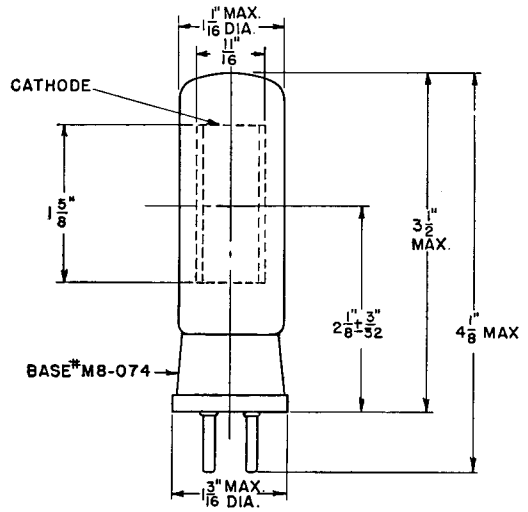
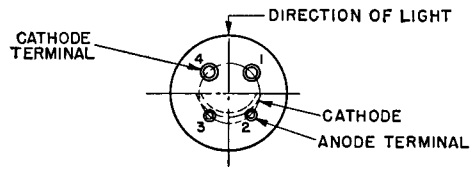
GENERAL ELECTRIC



TECHNICAL INFORMATION (CONT'D)



Mechanical

Base	medium 4-pin bayonet
Net weight, approx.	.2 ounces
Shipping weight, approx	.3 pounds
Operating position	vertical or horizontal with plane of electrodes vertical

MAXIMUM RATINGS AND TYPICAL OPERATING CONDITIONS

CLASS A AUDIO-FREQUENCY AMPLIFIER AND MODULATOR

	Typical Operation	Maximum Ratings	
D-c plate voltage	350	350	volts
Plate dissipation	....	7.5	watts
D-c grid voltage	−6	....	volts
Peak grid swing, approx.	6	....	volts
D-c plate current	2.8	....	milliamperes
Load resistance	40,000	....	ohms
Plate power output, less than 5% second harmonic	58	....	volts

CLASS B RADIO-FREQUENCY POWER AMPLIFIER

Carrier conditions per tube for use with a maximum modulation factor of 1.0

D-c plate voltage	350	350	volts
D-c grid voltage	−10	....	volts
D-c plate current	32	35	milliamperes
R-f grid current	....	2.5	amperes
Plate dissipation	9	10	watts
Output, approx.	2	....	watts

CLASS C RADIO-FREQUENCY POWER AMPLIFIER AND OSCILLATOR, PLATE MODULATED

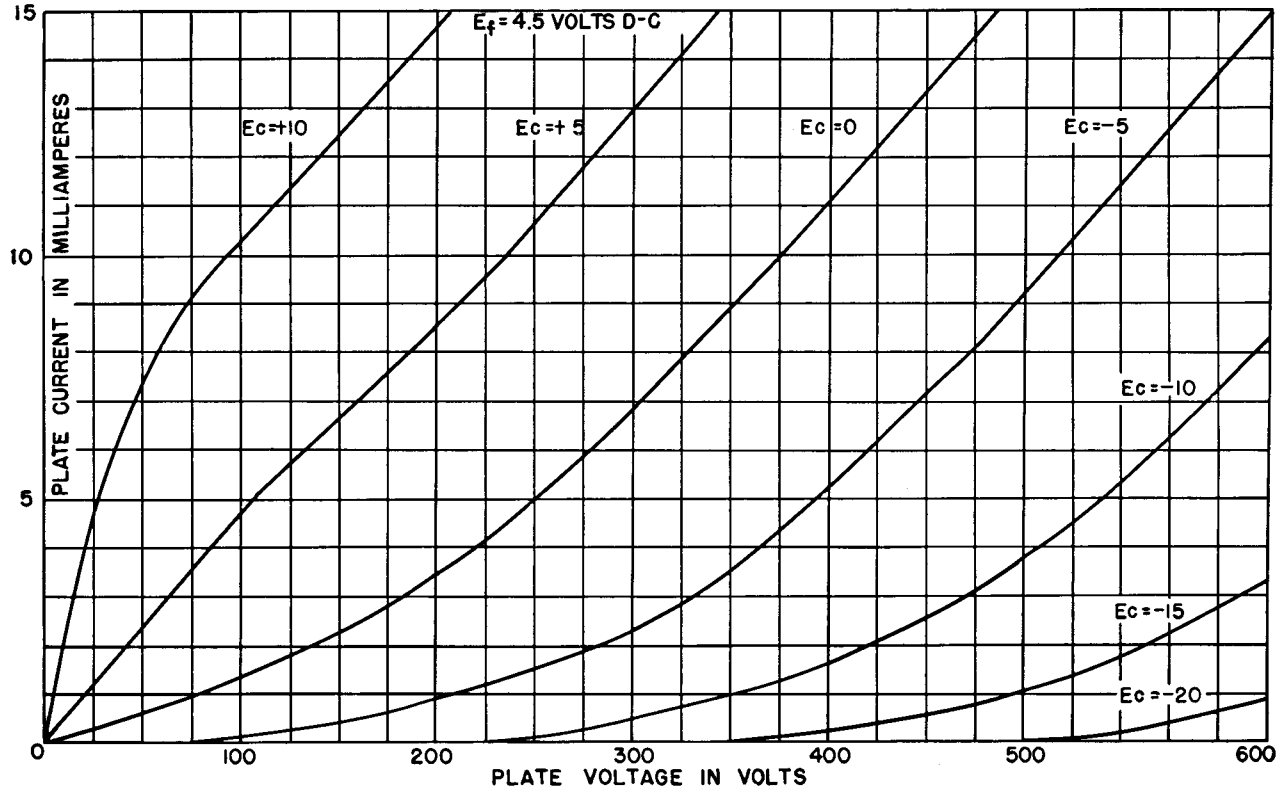
Carrier conditions per tube for use with a maximum modulation factor of 1.0

D-c plate voltage	300	300	volts
D-c grid voltage	−40	−100	volts
D-c plate current	35	40	milliamperes
D-c grid current, approx.	8	15	milliamperes
R-f grid current	....	2	amperes
Plate dissipation	5.5	10	watts
Plate power output, approx.	5	....	watts

CLASS C RADIO-FREQUENCY POWER AMPLIFIER AND OSCILLATOR

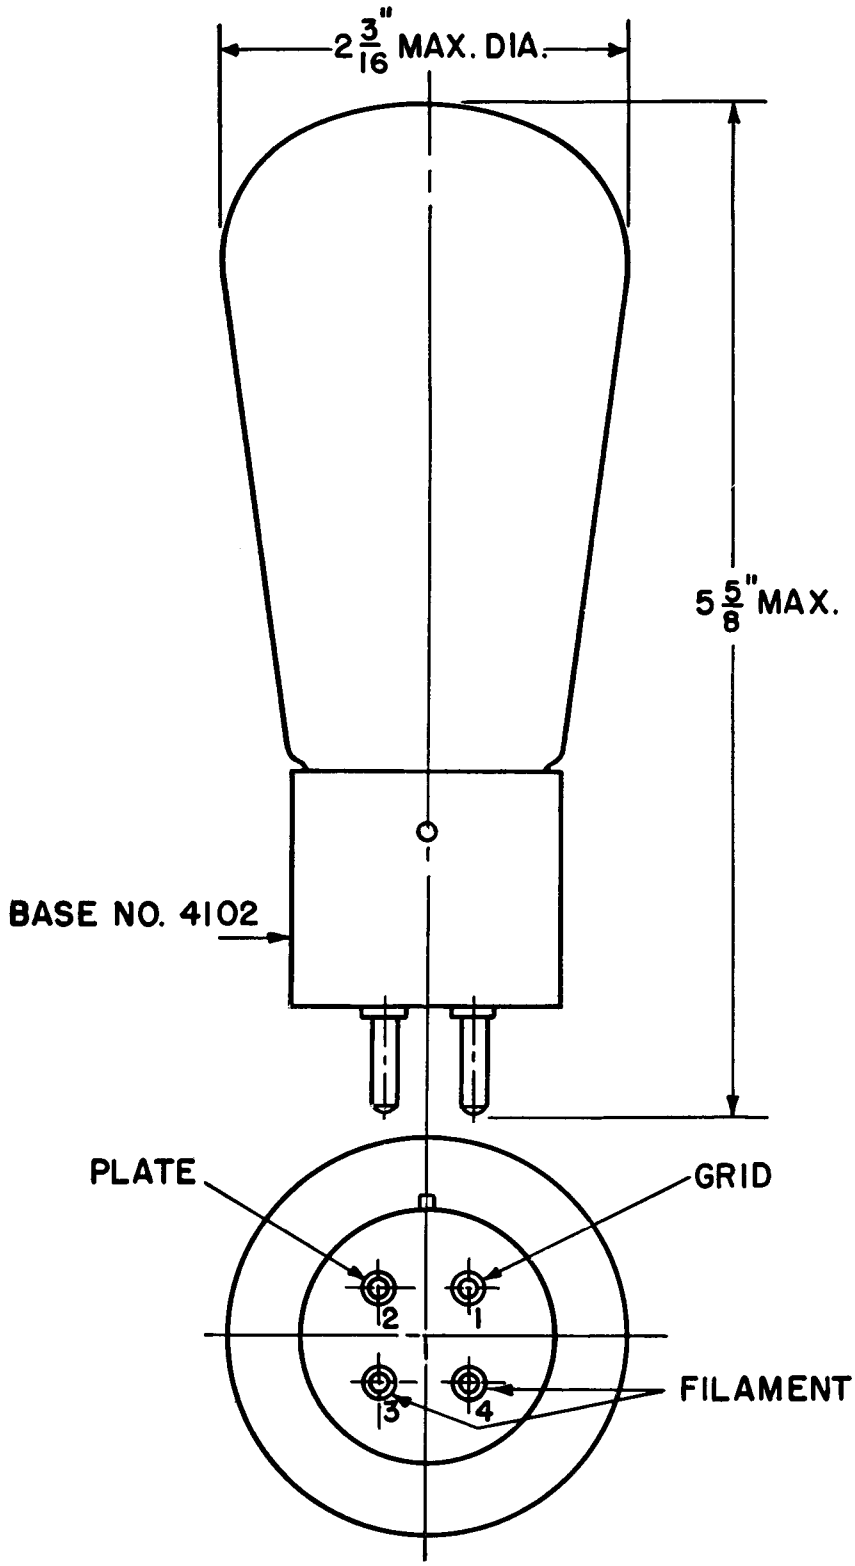
*Key-down conditions per tube without modulation**

D-c plate voltage	350	350	volts
D-c grid voltage	−25	−100	volts
D-c plate current	35	40	milliamperes
D-c grid current, approx.	5	15	milliamperes
R-f grid current	....	3	amperes
Plate dissipation	6	10	watts
Plate power output, approx.	6	....	watts



* Modulation, essentially negative, may be used if the positive peak of the audio-frequency envelope does not exceed 115 per cent of the carrier conditions.

APPLICATION NOTES



The PJ-7 can be operated at frequencies as high as six megacycles, and may be operated at higher frequencies provided the maximum values of plate voltage and power input are reduced as the frequency is raised (other maximum ratings are the same as shown above). The tabulation below shows the highest percentage of maximum plate voltage and power input that can be used up to 170 megacycles for the various classes of service. Special attention should be given to adequate ventilation of the bulb at these frequencies.

Frequency	6	45	170	megacycles
Class B, r-f	100	75	50	per cent
Class C, plate modulated or unmodulated	100	75	50	per cent

The normal value of grid leak, when the tube is used as an oscillator or r-f power amplifier (Class c), is in the neighborhood of 5000 ohms, although this may be replaced by a suitable fixed bias. If self-bias is used, the cathode resistor should be approximately 600 ohms.

*Continuous Commercial Service is defined as that type of service in which long life and reliability of performance under continuous operating conditions are the prime considerations.

†Intermittent Commercial and Amateur Service is defined as that type of service where minimum size, lightweight and maximum power output are more important than long life.

Intermittent operation implies that no 'on' period exceeds 5 minutes and an 'on' period is followed by an 'off' period of the same or longer duration.

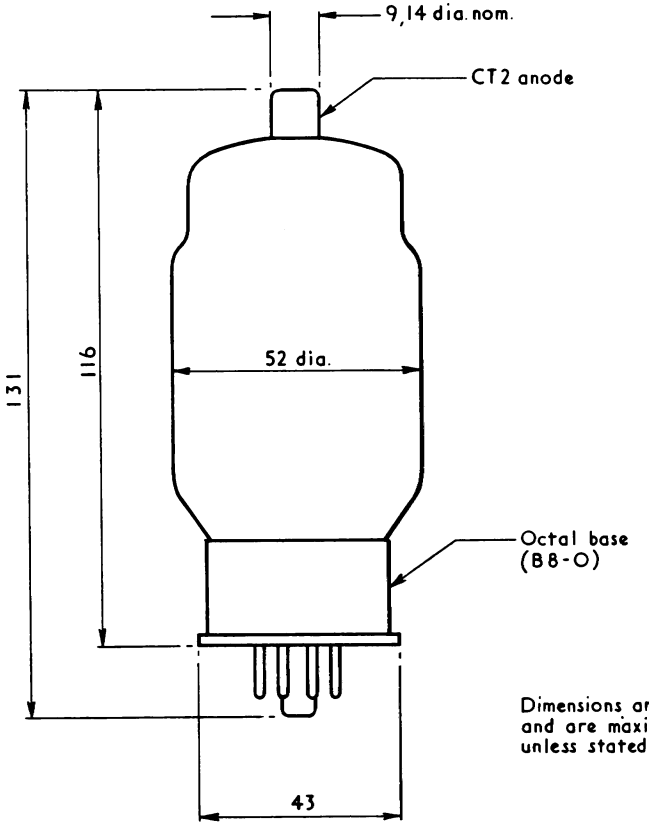
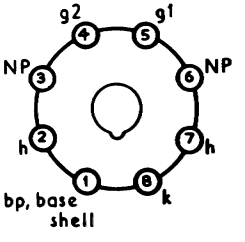
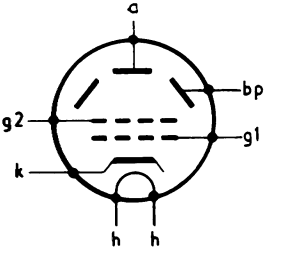
R_a	460	Ω
t_p	2	μs
PRF	1500	p/s



INSTALLATION



The tube may be mounted either vertically or horizontally. When a pair of tubes is mounted vertically it is recommended that the centres of the tube-holders are not less than 100mm apart and that pins 4 and 8 of each tube are in line. When a pair of tubes is mounted horizontally it is recommended that the centres of the tubeholders are not less than 100mm apart and that pins 4 and 8 of each tube are in the same vertical line. If circuit layout makes closer mounting desirable, free air circulation around the tube must be ensured, if necessary by means of a small fan. The bulb temperature under the worst operating conditions must not exceed 250°C.



OPERATING NOTES

In order to prevent parasitic oscillation, it is desirable to use a grid stopper resistor mounted close to the tubeholder. In Class AB1 audio circuits this may have a value up to 10kΩ reducing to about 100Ω in r.f. circuits, when an anode stopper consisting of a 100Ω ¼W resistor overwound with 2½ turns of 18 s.w.g. copper wire may also be necessary. The usual practice of using a single chassis point for all earth returns should always be adopted in r.f. equipment.

MAXIMUM RATINGS

Absolute-Maximum Values

Peak Inverse Plate Voltage	350	Volts
Steady-State Peak Plate Current	20	Milliamperes
DC Output Current	5.0	Milliamperes
Heater-Cathode Voltage		
Heater Positive with Respect to Cathode	50	Volts
Heater Negative with Respect to Cathode	50	Volts
Envelope Temperature at Hottest Point#	250	C

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

AVERAGE CHARACTERISTICS

Tube Voltage Drop		
Ib = 5.0 Milliamperes DC	2.6	Volts

* Publication of these data does not obligate the General Electric Company to manufacture a tube with these characteristics.

\+ The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

‡ Heater current of a bogey tube at Ef = 6.3 volts.

§ Without external shield.

¶ One method of mounting the Y-1012 is to use a stainless-steel "T" bolt (see drawing) to attach the mounting base of the tube to a chassis or circuit board. The "T" bolt should be inserted in the slot in the base of the tube, turned 90 degrees, and attached to the chassis or circuit board with a 2-56 nut and lock washer. Torque used to tighten the nut should not exceed 3 inch-pounds.

\# Operation below the rated maximum envelope temperature is recommended for applications requiring the longest possible tube life.

Envelope Temperature at Hottest Point▲	250	°C
Temperature Differential Between Two Adjacent Electrodes□	75	°C
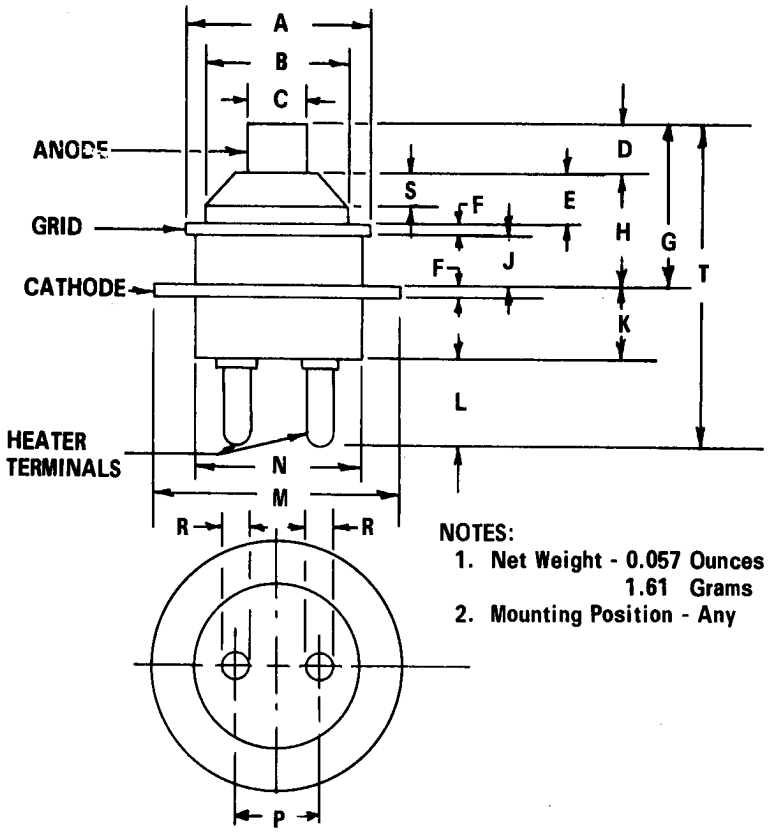
Mechanical Vibration (20-2000 Hz Sinusoidal)	10	G Peak

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron device of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The device manufacturer chooses these values to provide acceptable serviceability of the device, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the device under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any device under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the device under consideration and of all other electron devices in the equipment.



NOTES

▲ For specific recommendations concerning higher temperature operation, contact your General Electric sales representative.

□ This assumes no thermal heat sinking to any insulator.

The devices and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of devices by General Electric Company conveys any license under patent claims covering combinations of these devices with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of these devices with other devices or elements by any purchaser or others.

Planar Triode

Y-1692

Development Type ★

The Y-1692 is a triode of ceramic-and-metal planar construction intended for use as a CW amplifier or oscillator at frequencies up to 2500 megacycles. The Y-1692 is specifically designed for lower voltage-higher current applications.

CHARACTERISTICS AND TYPICAL OPERATION

NOTES

★ Both electrical and mechanical characteristics of development types are subject to change; therefore it is recommended that designers consult their General Electric field representative before designing equipment around developmental types.

● The equipment designer should design the equipment so that heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

♦ Measured at 450 KHz using a grounded adapter that provides shielding between external terminals of tube.

§ To be determined.

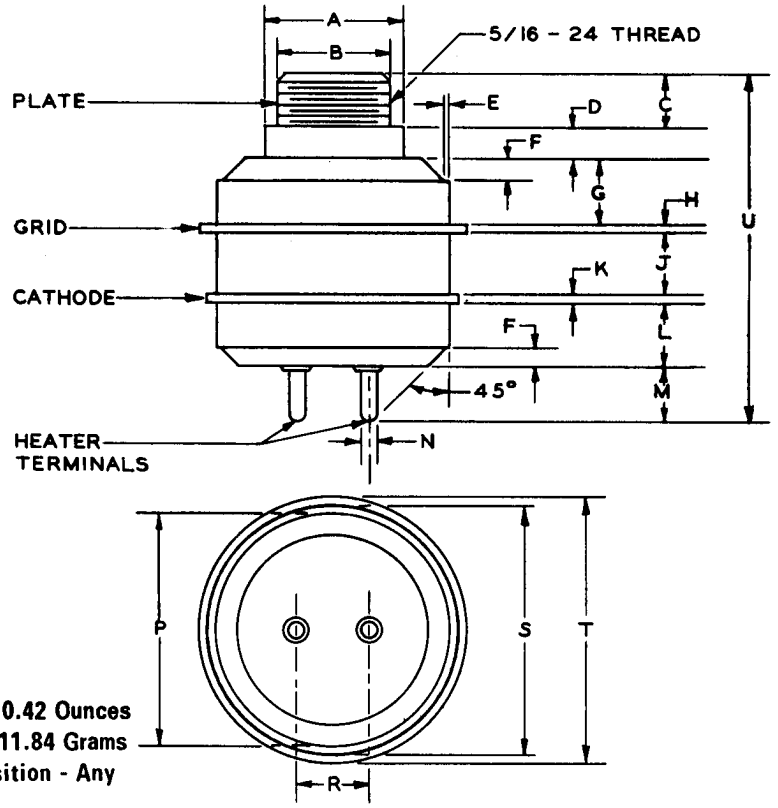
Mechanical Vibration (20-2000 Hz Sinusoidal)	30	G Peak

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron device of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The device manufacturer chooses these values to provide acceptable serviceability of the device, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the device under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any device under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the device under consideration and of all other electron devices in the equipment.

NOTES



⊕ With adequate heat sink attached to threaded plate stud.

▲ For specific recommendations concerning higher temperature operation, contact your General Electric sales representative.

□ This assumes no thermal heat sinking to any insulator.

The devices and arrangements disclosed herein may be covered by patents of General Electric Company or others. Neither the disclosure of any information herein nor the sale of devices by General Electric Company conveys any license under patent claims covering combinations of these devices with other devices or elements. In the absence of an express written agreement to the contrary, General Electric Company assumes no liability for patent infringement arising out of any use of these devices with other devices or elements by any purchaser or others.

—PRODUCT INFORMATION—

Planar Triode

Y-1763

Development Type ⋆

The Y-1763 is a planar ceramic triode with exceptionally large cathode area. This results in the ability to develop high values of peak power at lower current densities resulting in longer tube life. The ability to dissipate large amounts of heat produces high power capabilities under high duty pulsed and CW conditions.

DISPLAY DEVICES

—PRODUCT INFORMATION—

Low Voltage Indicator Tube

Y-1938

TENTATIVE SPECIFICATION SHEET

The Y-1938 is a low voltage seven bar segment vacuum cathodoluminescent readout tube which provides bright, sharp display of alphanumeric symbols at low drive and power levels. Symbols are displayed in type Y-1938 by excitation of phosphor-screened segments, which are energized by electrons emitted by a directly heated common cathode.

LOW POWER - Typical operation for high brightness is 25 volts for anode and 1.5 Vac or Vdc at 42 mA for the cathode.

FAST SPEED - Operates in the very high speed range through the use of low presistence phosphor.

BRIGHTNESS - Displays a highly visible blue-green color approximately 200 foot-lamberts.

WIDE ANGLE VIEWING - Single plane character formation with no parallax problems and up to 150° viewing range.

RELIABILITY - Long life construction that uses a single plane and thick film technology combined with the low total power requirements of less than 200 milliwatts.

CHARACTER SIMPLIFICATION - Only one type to display digits (0-9), letters - A, C, E, F, G, H, I, J, L, O, P, S, U, Y.

COMPACT SIZE - Standard miniature T6½ bulb, two inches maximum height for minimum space requirements.

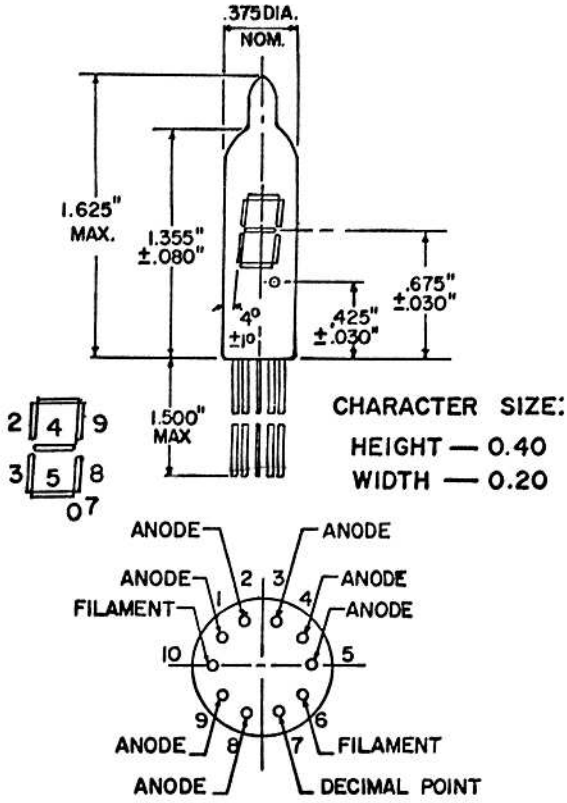
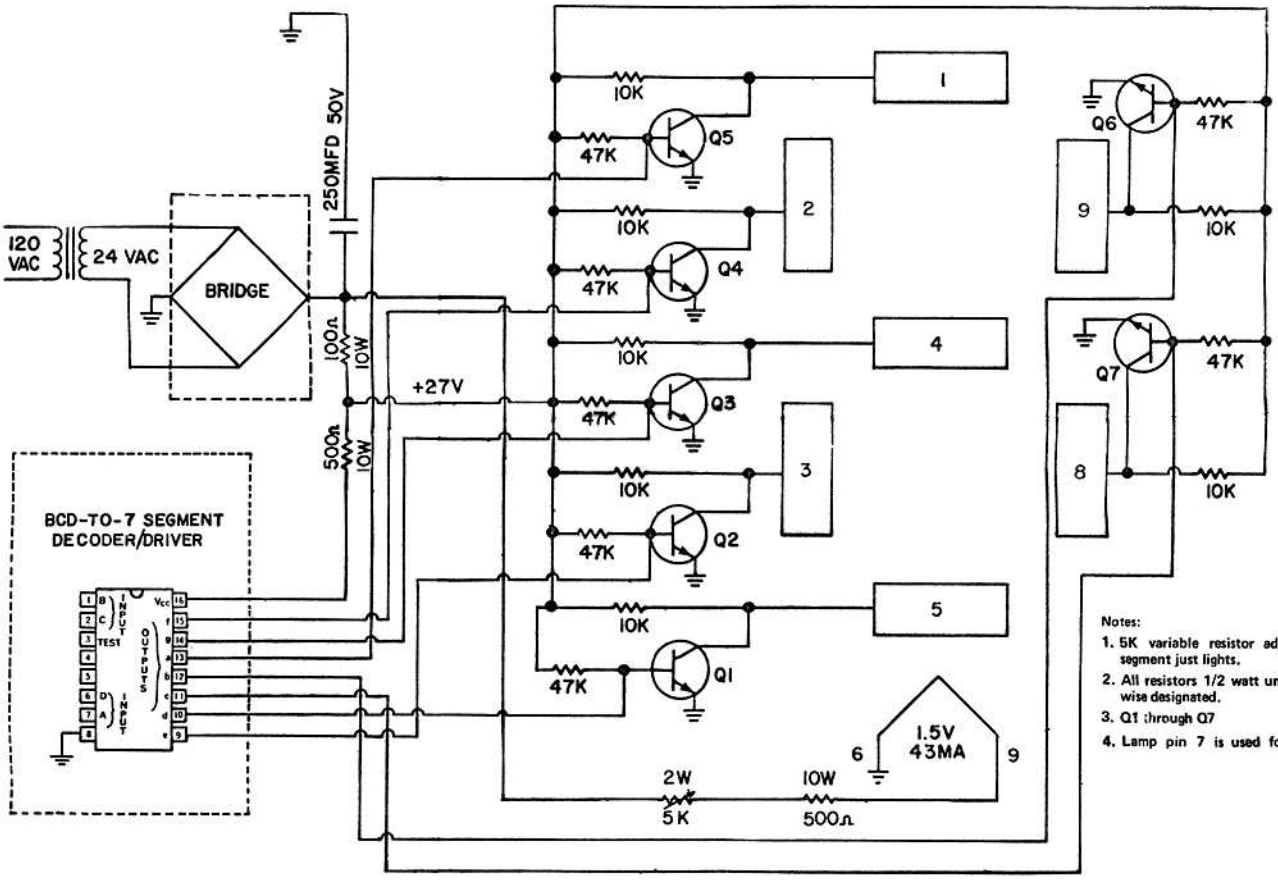
SEVEN SEGMENT DIGITAL FLUORESCENT DISPLAY



TYPE Y-4075

The readout tube provides a bright, sharp display of numerals at low drive and power levels at a very fast speed. Numbers are displayed by excitation of phosphor-screened segments, which are energized by electrons emitted by a directly heated cathode.



FEATURES

1. Driven by a 7447 BCD to seven segment Decoder/Driver.
2. Total power requirements of less than 175 MW.
3. Fluorescent segments are mounted on a single substrate for extra durability in portable applications.
4. Highly visible blue-green color. Easy on the eye.
5. Typical light output of 200 foot lamberts at 25 volts D.C.
6. Maximum allowable segment voltage is 35 volts D.C.

	UNIT	SEG. V.	FIL. V.	MIN.	NOM.	MAX.
Filament current	MA. AC/DC	27	1.2	35	40	45

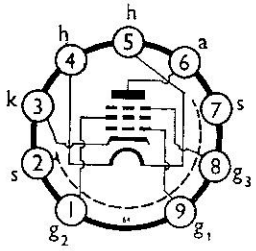
Average brightness	Ft/lambert	27	1.2	100	200	–

PIN CONNECTIONS
Bottom View

Notes:
1. 5K variable resistor adjusts until segment just lights.
2. All resistors 1/2 watt unless otherwise designated.
3. Q1 through Q7
4. Lamp pin 7 is used for decimal.

G.E.C. VALVES

LOW NOISE AF PENTODE 6·3V INDIRECTLY HEATED



Z729/EF86

ISSUE 2

The Z729 is a commercial equivalent of CV2901.

An indirectly heated pentode with low hum and low microphony, suitable for use in low level low frequency amplifiers, measuring instruments, industrial control circuits, etc. Its low grid current makes it particularly useful in circuits requiring a high input impedance.

Printed in England. C.

The Z729/EF86 may be classed as intermediate between an electrometer valve and one of normal design because of the small grid current to be expected.

In all applications where low grid current is important it is essential to ensure that the grid is always negative with respect to cathode by at least 1·7V in order to avoid positive grid current due to the interception of electrons by the grid. The magnitude of the negative grid current depends upon operating conditions and limits the value of maximum external resistance between grid and cathode. Under d.c. conditions the grid current varies roughly as $(V_a \times p_a + V_{g2} \times p_{g2})$. Under the conditions shown in the data sheet under "Characteristics," the grid current does not normally exceed 0·2μA and is usually less than 0·05μA. A valve that has been stored for some time may have a higher grid current initially but will settle to a satisfactorily low value if operated for a few minutes under normal conditions with a low value of grid resistor.

If the valve is used under conditions of maximum voltage and dissipation, the external grid to cathode resistance should not exceed 1MΩ with fixed bias or 2MΩ with cathode bias in order to obtain satisfactory operation with all valves. Permissible grid to cathode resistance values at reduced voltages and dissipations are given below and apply to both triode and pentode operation.

The majority of valves will operate satisfactorily with resistance values up to four times those shown and advantage may be taken of this when selection is possible. However, it is advisable not to exceed 100MΩ.

Maximum External Grid to Cathode Resistance with Fixed Bias

V_a	$R_{g-k(max)}$ at $p_{a+g2(max)}$ =			
	1·2W	0·5W	0·2W	0·1W
300V	1MΩ	2·5MΩ	6MΩ	12MΩ
200V	1·5MΩ	3·75MΩ	9MΩ	18MΩ
100V	3MΩ	7·5MΩ	18MΩ	36MΩ

These values may be doubled for cathode bias.

The above table values applies to applications in which the operating point is determined by a specified grid bias with respect to cathode. On the other hand, any valve may be operated with the grid left floating and the grid will then adjust itself to the crossover potential at which the grid current curve passes through zero. In the Z729/EF86 this occurs normally at about $V_g = -1{\cdot}3V$. Although this method is useful for certain special applications, the incremental input impedance is extremely variable, ranging typically between 1MΩ and 50MΩ because of the rapid rise of positive grid current.

AF AMPLIFIER OPERATION AND HUM

The Z729/EF86 is normally used as an RC coupled pentode amplifier as shown in fig. 1. For exceptionally low noise applications, the valve may be used as a triode by connecting the anode, suppressor and screen together, and fig. 2 gives the performance to be expected. When high impedance circuits are possible, very high gain is obtainable as shown by the curve of fig. 4.

To obtain minimum hum pickup, the heater connections should be twisted together for three or four inches and kept as far as possible from the grid contact. A valve socket having low leakage and low capacitance between contacts is required, preferably of porcelain or PTFE with a central screening boss, this being earthed together with contacts 2 and 7 which connect to the valve internal screening system. The suppressor (pin 8) is normally earthed but it may be connected to the cathode. Special precautions have been taken to reduce to a minimum the grid/heater capacitance in order to render

the valve relatively insensitive to an unbalanced heater supply. Similar precautions must be taken with external components. Normally a centre-tapped 6·3V supply will be used with the tap earthed. The hum pickup with a 470kΩ grid resistor will then be less than 1·5μV referred to the grid. The use of a higher or lower grid resistance will modify the hum pickup proportionally. A balancing resistor may be used if desired and in some cases this will reduce the hum by approximately 1-2dB. If even this hum level is still too high, a d.c. heater supply must be used.

As the total anode and screen current is very low in most applications, it is sometimes convenient to obtain a very smooth, stable, hum-free and low noise h.t. supply from a standard 120V battery.

To avoid hum pickup, etc., in the input circuit, care must be taken to avoid coupling with higher signal level circuits, bearing in mind the possibility that the chassis itself can be responsible for such coupling.

In order to maintain a low hum level it is essential to bypass any cathode bias resistor with a suitably large capacitor of at least 500μF. At higher signal levels part of the cathode resistance may be left unbypassed when negative feedback is necessary, or for tone control purposes.

At audio frequencies the screen in the pentode circuit should be bypassed to earth with a paper capacitor of at least 0·1μF.

Acoustic feedback is not normally encountered in the Z729/EF86 as it is especially anti-microphonic and it is not usually necessary to use special techniques such as a separate flexibly mounted and weighted sub-chassis, except in extreme cases as when the valve is close to a loudspeaker or when considerable vibration is present. The internal screening renders an external screening can unnecessary but one may be used as a retainer when necessary.

The Z729/EF86 may be used in a 0·3A series heater chain if the heater is shunted by a 63Ω resistor. This resistor should be rated at 5W since it will carry 0·3A if the valve is removed. The heater should be connected into the earthy end of the chain.

INDUSTRIAL APPLICATIONS

The Z729/EF86 has many applications in the industrial field because of its high order of stability and its freedom from unwanted effects. A high value grid resistor may be used when required because of the low grid current. The valve is ideal for photocell circuits and will show a considerable increase in sensitivity over valves normally used hitherto.

Many requirements in test equipment can be fulfilled by the Z729/EF86 ; a valve voltmeter, for example, needs a very stable valve characteristic and a suitable circuit is given in fig. 3. Certain component values are not given since they depend upon the ranges required but the resistors associated with the range switch may total 10-20MΩ.

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should de ign so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

SPECIAL TESTS AND RATINGS

Stability Life Test
Statistical sample operated for twenty hours to evaluate and control initial variations in transconductance.

Survival Rate Life Test
Statistical sample operated for one hundred hours to evaluate and control early-life electrical and mechanical inoperatives.

Heater-Cycling Life Test
Statistical sample operated for 2000 cycles to evaluate and control heater-cathode defects. Conditions of test include Ef = 7.5 volts cycled for one minute on and one minute off, Eb = Ec = 0 volts, and Ehk = 135 volts with heater positive with respect to cathode.

Shock Rating - 600 G
Statistical sample subjected to five impact accelerations of 600 G in each of four different positions. The accelerating forces are applied by the Navy-type, High Impact (flyweight) Shock Machine for Electronic Devices or its equivalent.

Fatigue Rating - 10 G
Statistical sample subjected to vibrational acceleration of 10 G for 48 hours minimum in each of two different positions. The sinusoidal vibration is applied at a fixed frequency between 25 and 60 cycles per second.

Altitude Rating - 100000 Feet
Statistical sample subjected to pressure of 8.0 millimeters of mercury to evaluate and control arcing and corona.

Note: The conditions for some of the indicated tests have deliberately been selected to aggravate tube failures for test and evaluation purposes. In no sense should these conditions be interpreted as suitable circuit operating conditions.

* Publication of these data does not obligate the General Electric Company to manufacture a tube with these characteristics.

\+ The equipment designer should design the equipment so that the heater voltage is centered at the specified bogey value, with heater supply variations restricted to maintain heater voltage within the specified tolerance.

‡ Heater current of a bogey tube at Ef = 6.3 volts.

§ Without external shield.

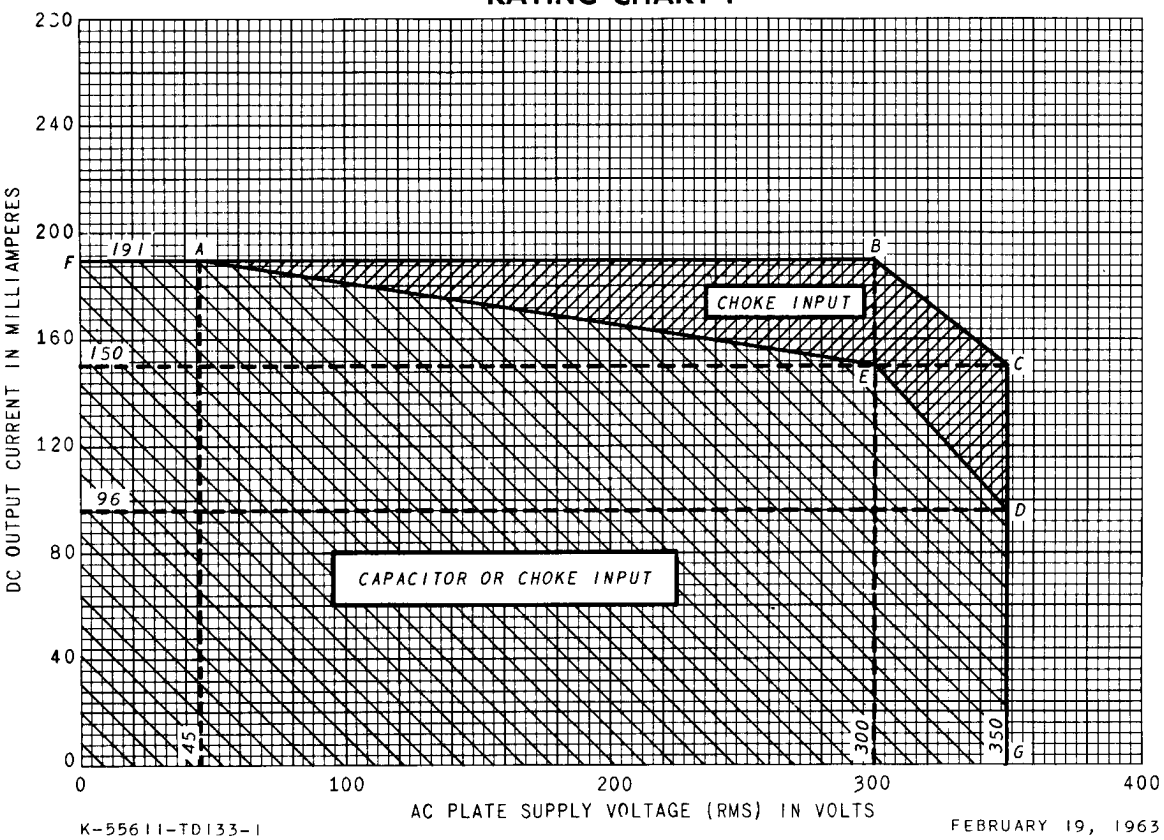
→ Tube Voltage Drop Ib = 300 Milliamperes	37	Volts

* Publication of these data does not obligate the General Electric Company to manufacture a tube with these characteristics.

\+ To simplify the application of the maximum ratings to circuit design, the Absolute-Maximum ratings are presented in chart form as Rating Charts I, II, and III. Rating Chart I presents the maximum ratings for a-c plate-supply voltage and d-c output current. Rating Chart II provides a convenient method for checking conformance with the maximum steady-state peak-plate-current rating. Rating Chart III offers a convenient method for checking conformance with the maximum transient peak-plate-current rating. Rating Chart I applies to both capacitor-input and choke-input filters, while Rating Charts II and III apply to capacitor-input filters only.



Operating points should be so selected that the boundary limits of a-c plate-supply voltage and d-c output current on Rating Chart I, and maximum d-c output current per plate and rectification efficiency on Rating Chart II, are not exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, and environmental conditions. On Rating Chart I the boundary FAEDG defines the limits for capacitor-input filter operation, and the boundary FABCDG defines the limits for choke-input filter operation.

Rating Chart III shows the minimum value of plate-supply resistance (Rs) required to remain within the transient peak-plate-current rating. The value of Rs should be such that it lies to the left of the line on Rating Chart III at the highest probable value of line voltage.

Z-5099-A*

PLANAR TRIODE

The Z-5099-A is a high-mu triode for use in grounded-grid Class C power amplifiers, oscillators, or frequency multipliers at frequencies up to 2500 megacycles. Typical power output is 19 watts at 2500 megacycles and 40 watts at 500 megacycles. The metal-ceramic construction permits the tube to withstand shock tests at 400G. The specially designed radiator enables the plate to dissipate 100 watts with conduction cooling when a heat sink sufficient to limit the seal temperature to 200 C maximum is used.

The Z-5099-A features graduated-diameter disk seals for maximum efficiency in cavity and parallel-line circuits thus assuring both low lead inductances and electrode isolation. Other features include high transconductance and low interelectrode capacitances.

GENERAL

Electrical

Cathode - Coated Unipotential

Heater Characteristics and Ratings

DC Grid Current	50	Milliamperes
Plate Dissipation	70	Watts
Grid Dissipation	2.0	Watts
Frequency	2500	Megacycles

Absolute-Maximum ratings are limiting values of operating and environmental conditions applicable to any electron tube of a specified type as defined by its published data and should not be exceeded under the worst probable conditions.

The tube manufacturer chooses these values to provide acceptable serviceability of the tube, making no allowance for equipment variations, environmental variations, and the effects of changes in operating conditions due to variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

The equipment manufacturer should design so that initially and throughout life no absolute-maximum value for the intended service is exceeded with any tube under the worst probable operating conditions with respect to supply-voltage variation, equipment component variation, equipment control adjustment, load variation, signal variation, environmental conditions, and variations in the characteristics of the tube under consideration and of all other electron devices in the equipment.

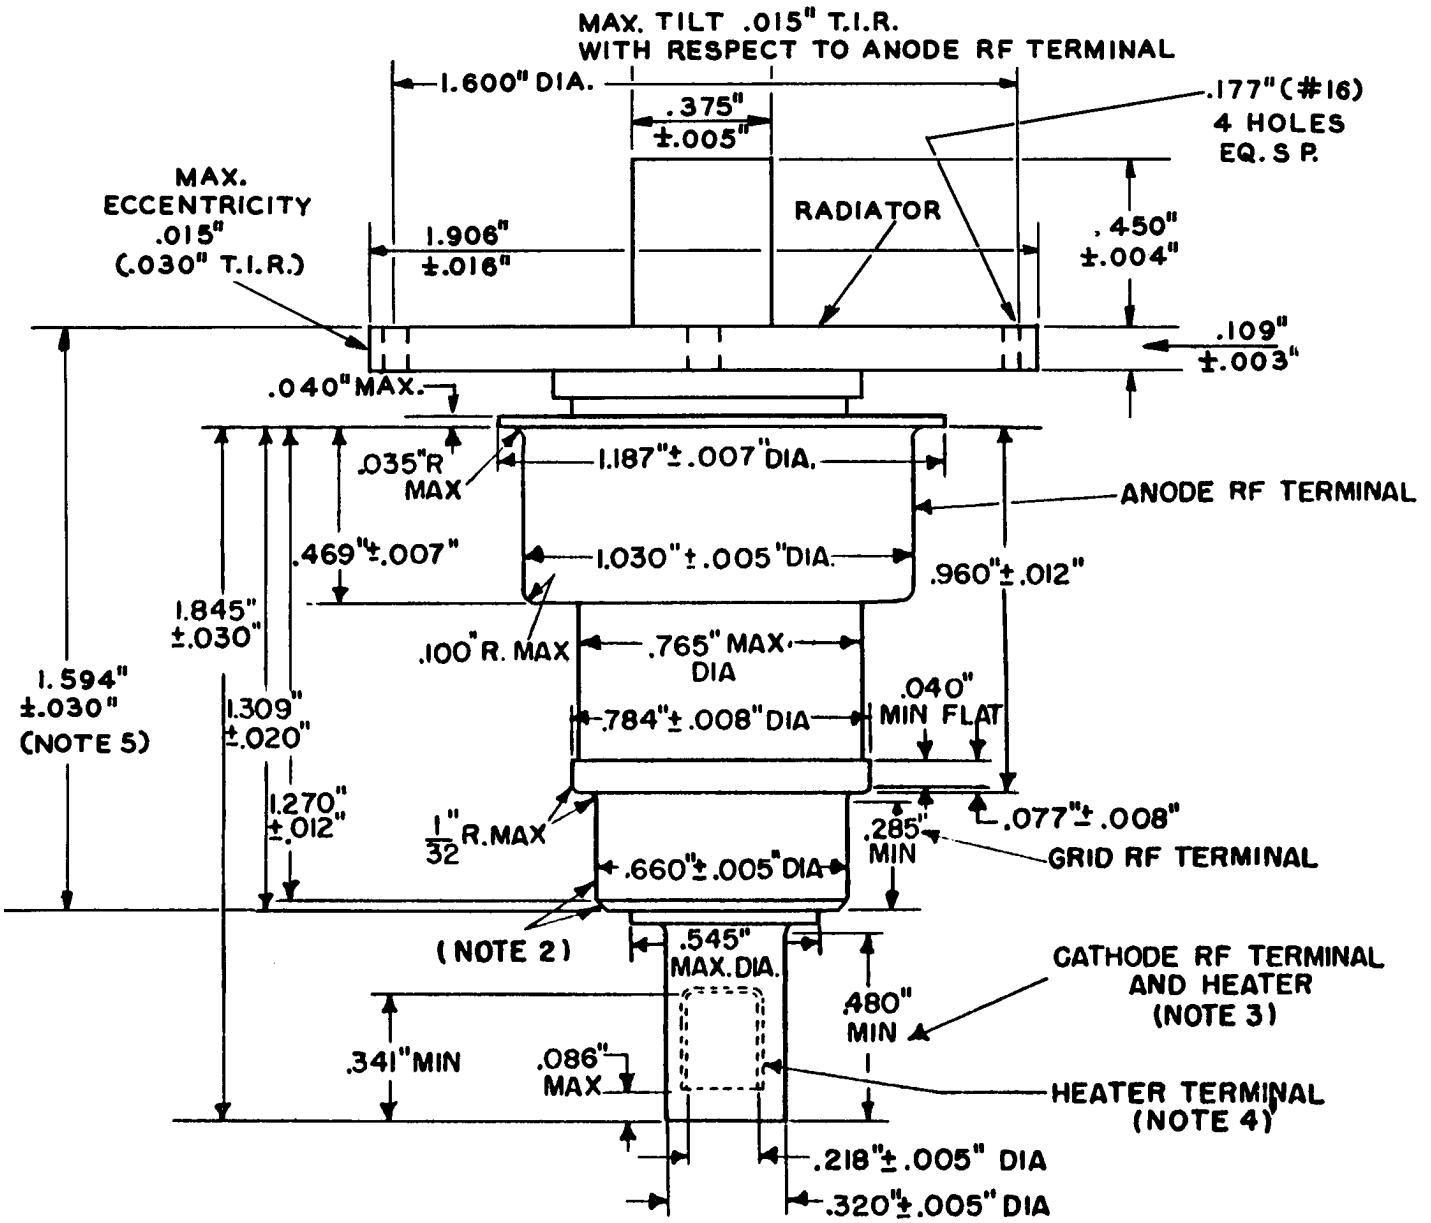
DC Grid Voltage	-40	-22	Volts
Useful Power Output	40	19	Watts

* Publication of these data does not obligate the General Electric Company to manufacture a tube with these characteristics.



\+ The Z-5099-A operates at frequencies where it is necessary to consider transit-time effects of the electron current. The principal effects influencing tube operation are the decrease in power output and operating efficiency with increase in frequency, and the bombardment and heating of the cathode by electrons from the region of the grid, which can be severe enough to result in short tube life and erratic operation. Operating frequency, circuit design and adjustment, grid bias, and grid current contribute to the degree of cathode bombardment. There is an optimum heater voltage which will maintain the cathode at the correct operating conditions. If the conditions of operation result in appreciable cathode back-heating, it may be necessary to start dynamic tube operation at normal heater voltage, followed by a reduction of heater voltage to the proper value. A maximum variation of plus or minus five percent in heater voltage is recommended where extended tube life is a factor.

‡ Heater current of a bogey tube at Ef = 6.3 volts.

§ Measured in a special shielded socket.

¶ For modulation factors less than 1.0, a higher d-c plate voltage may be used if the sum of the peak positive audio voltage and the d-c plate voltage does not exceed 1200 volts.

Supersedes 9/20/62 (B)

NOTES:

1. External metal parts plated with 30 MSI minimum of copper and/or silver.
2. Solder not to extend radially beyond RF terminal.
3. The cathode RF terminal and grid RF terminal concentric with respect to the anode terminal within 0.020" (runout within 0.040").
4. The heater terminal concentric with respect to the cathode RF terminal within 0.012" (runout within 0.024").
5. Measure at two diametrically opposite points and average reading.

OBJECTIVE FOR DEVELOPMENTAL TYPE

Z-5267*

PLANAR TETRODE

The Z-5267 is a planar tetrode primarily designed for grounded-grid radio-frequency power amplifier or oscillator service at frequencies to 3000 mc and beyond.

The Z-5267 combines small interelectrode spacings with a thermally stable electrode structure and low lead inductance. The envelope and electrode terminals are designed for efficient utilization of cavity resonators at the higher frequencies and of line-type and lumped-constant circuits at the lower frequencies.

OBJECTIVE FOR DEVELOPMENTAL TYPE

Z-5387*

PLANAR TRIODE

The Z-5387 is a high-mu, metal-and-ceramic planar triode for use at very-high and ultra-high frequencies in grounded-grid, Class C CW or pulsed, power-amplifier, oscillator, or frequency-multiplier circuits. In such service it will operated from the low frequencies to above 3000 megacycles. Cooling of the tube envelope is accomplished by conduction from the contact circuit members with sufficient additional forced air to limit the maximum temperature at 250 C.

The tube has an oxide-coated indirectly-heated cathode of planar-electrode construction. The metal-and-ceramic envelope holds concentricity to extremely close limits. The strength inherent in the structural design allows shock-testing at 400 g. Graduated-diameter disk seals assure maximum efficiency in the use of cavity and parallel-line circuits with the resultant desirable features of both low lead inductances and electrode isolation. Radio-frequency losses in the tube are kept to a minimum by the special techniques and materials used. Other features of the tube are high transconductance and low interelectrode capacitances.

GENERAL

Electrical

Peak Plate Current	1.9	Amperes
Peak Grid Current	1.1	Amperes
Driving Power during Pulse, approximate	400	Watts
Peak Useful Power Output, approximate	1500	Watts

* Publication of these data does not obligate the General Electric Company to manufacture a tube with these characteristics.

\+ The Z-5387 operates at frequencies where it is necessary to consider transit-time effects of the electron current. The principal effects influencing tube operation are the decrease in power output and operating efficiency with increase in frequency, and the bombardment and heating of the cathode by electrons from the region of the grid which can be severe enough to result in short tube life and erratic operation. Operating frequency, circuit design and adjustment, grid bias, and grid current contribute to the degree of cathode bombardment. There is an optimum heater voltage which will maintain the cathode at the correct operating temperature for a particular set of operating conditions. If the conditions of operation result in appreciable cathode back heating, it may be necessary to start dynamic tube operation at normal heater voltage followed by a reduction of heater voltage to the proper value. A maximum variation of plus or minus five percent in heater voltage is recommended where extended tube life is a factor. Under all other conditions, the variation in heater voltage should not exceed plus or minus ten percent. For application above 400 megacycles, recommendations are to be obtained from the tube manufacturer regarding the heater voltage to be used under a specific set of operating conditions.

‡ Where long life and reliable operation are important, lower tube envelope temperatures should be used.

2/19/63 (B)
Supersedes 4/22/60 (B)

NOTES:

1. External metal parts (except radiator) plated with 30 msi of copper and /or silver.
2. Solder not to extend radially beyond grid RF terminal.
3. Total indicated runout of the grid-contact surface and the cathode-contact surface with respect to the anode shall not exceed 0.020"
4. Total indicated runout of the cathode-contact surface with respect to the heater-contact surface shall not exceed 0.012".
5. Only this flange to be used as a socket stop and clamp.

IMAGE ORTHICON

Focus – Magnetic Deflection – Magnetic

The Z-5395 is an image orthicon with a wide-spaced high-gain thin film target and an S-1 photosurface. The good sensitivity of the S-1 photosurface to radiation in the red and near infra red regions makes the tube suitable for detection and televising of scenes which are illuminated with or consist of infra red sources.

By appropriate choice of infra red filtered light sources for illumination, scenes which appear to be in total visual darkness can easily be televised. In addition, useful pictures of objects at elevated temperatures which are not visibly hot can be obtained.

The very low sideways leakage characteristics of the thin film target adapts the tube to applications where the signal is stored for a very long period before being read out. This permits the attainment of additional sensitivity by the use of low frame rates or beam pulsing.

Additional advantages due to the unique construction of the Z-5395 target are high amplitude response, reduction in redistribution of target secondary electrons, and minimized possibility of permanent burn-in damage from stationary image highlights.

Future design objectives for the tube are primarily in the areas of increased ruggedness, minimization of microphonics, increased red sensitivity, and improved temperature, sensitivity and stability relationships.

GENERAL		
Electrical

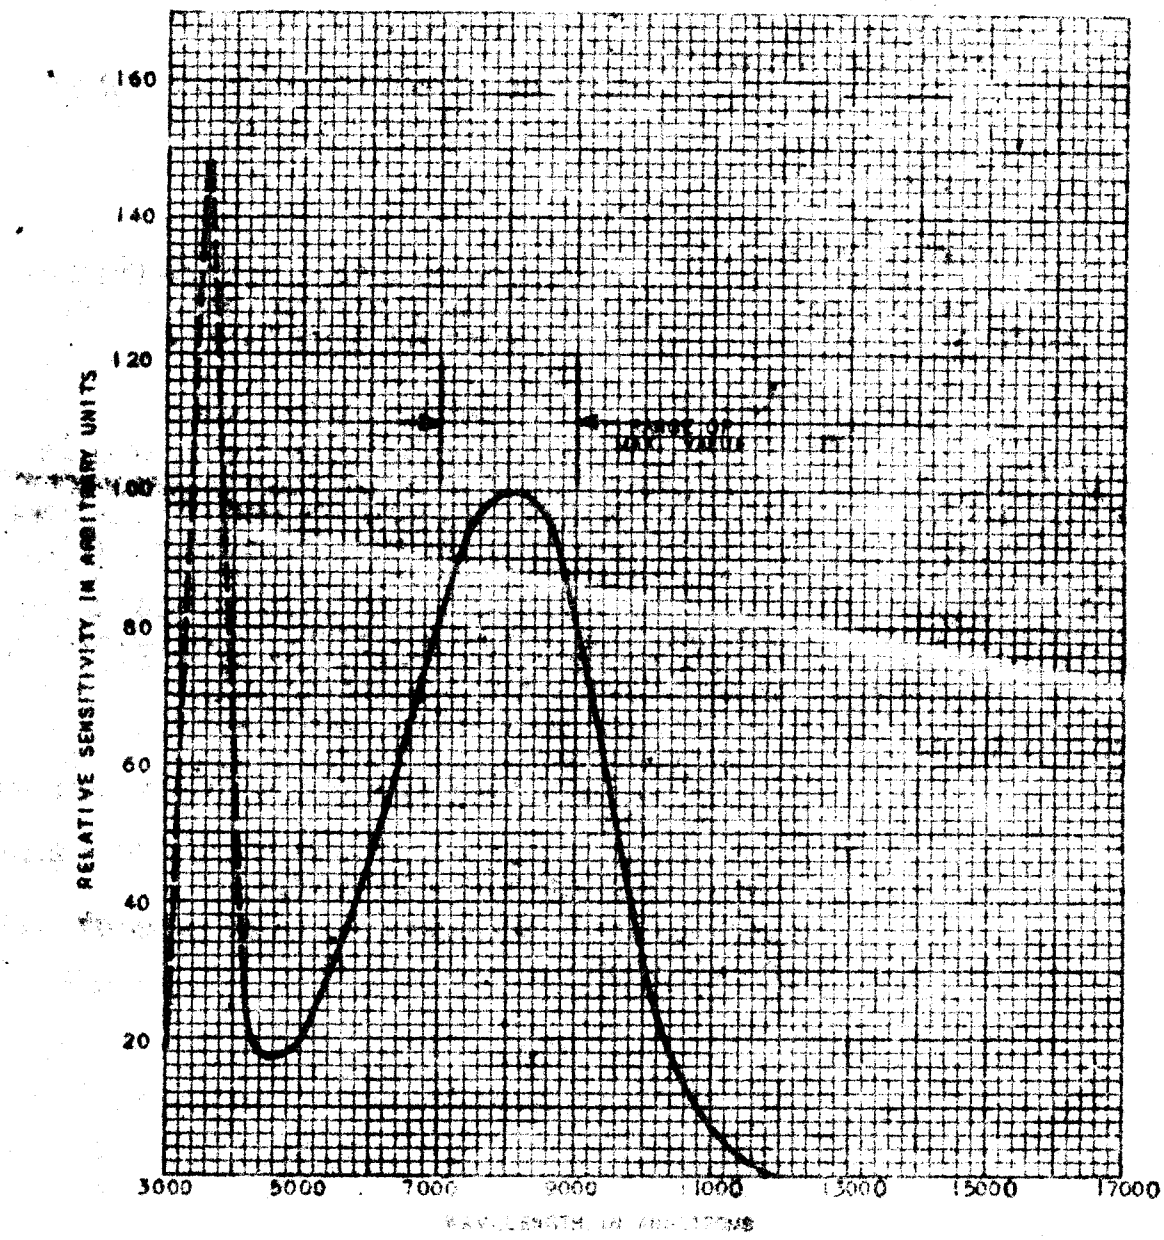
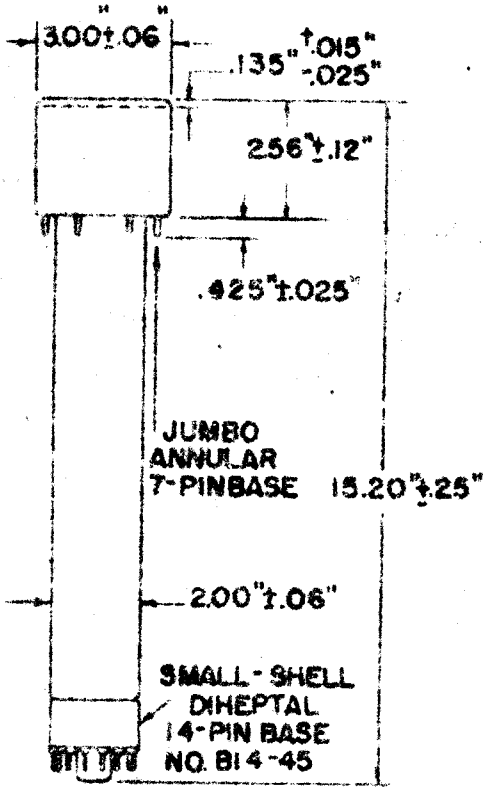
Sensitivity				
Photocathode, luminous with 2870 K tungsten light source	8	12	...	Microamperes
Photocathode ¶, percentage of infra red response with stock thickness, Corning #2540 and 2870 K tungsten light source	2.0	5.0	...	Percent

* Ratio of dynode voltages is shown under Typical Operation.

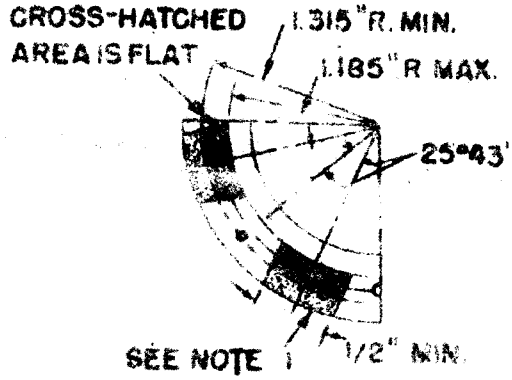
+ Adjust to give the most uniformly shaded picture near maximum signal.



‡ Direction of current should be such that a north-seeking pole is attracted to the image end of the focusing coil with the indicator located outside of and at the image end of the focusing coil.



§ The maximum temperature rating should not be exceeded since too high a bulb temperature may cause the more volatile components of the photocathode and dynode surfaces to redistribute with consequent decrease in life and sensitivity of the tube. The use of a fan on the tube is recommended.



¶ A small temporary loss of infra red sensitivity may occur after long periods of operation. This sensitivity should recover almost completely during idle periods.

For most stable operation, the use of the average photocathode current below the maximum rated value of 10 microamperes is recommended. Maximum life and most stable sensitivity characteristics will be obtained by using the lowest values of average photocathode current which are consistent with good picture quality.

IMAGE ORTHICONS

FOCUS-MAGNETIC **DEFLECTION-MAGNETIC**

These low-light-level image orthicons are designed to meet a wide variety of requirements for industrial, military, and scientific applications. They provide an effective low-light-level sensitivity down to 1.5 x 10^{-7} foot-candles photocathode illumination for resolution of 100 television lines per target inch. The GL-7967 is designed for normal environmental operation. The Z-7806 is a ruggedized version designed to operate under severe shock and vibration conditions.

Both tubes feature a high-gain, thin-film magnesium-oxide target with a sensitivity ten to twenty times that of glass targets. The extreme thinness and the anisotropic property of this semiconductor target virtually eliminates lateral leakage and increases the resolution 25 to 50 percent over that of standard glass targets. Since operation of the target depends on electron conduction, which is not a depletion process, rather than on ion conduction, permanent stickiness and burn-in are virtually eliminated. Low gamma permits a very wide operating range.

These and other features of these image orthicons assure long life and reliable operation in such applications as underwater observation, missile detection and tracking, and astronomical study of stars to the twentieth magnitude. The tubes are also suitable for service in scintillation experiments with the use of an image intensifier.

Field Strength of Alignment Coil, approximate#	0–3	0–3	Gausses

† Although these tubes will operate in standard equipment, modification to permit operation at these values will improve effective sensitivity for most applications.

‡ These values will permit the best low-light-level-sensitivity capability of the tube to be realized and will assure the maximum useful multiplier gain required in extreme low-light-level applications. The resolution sensitivity information in this data sheet was derived with these higher multiplier voltages.

§ Adjust to give the most uniformly shaded picture near maximum signal.

‖ 75 to 85 percent of photocathode voltage.

¶ The target supply voltage should be adjustable from −3 to +5 volts with blanking voltage off. Maximum target voltage is +10 volts above target cutoff. Recommended target voltage is +2 volts above cutoff. Slight readjustment, usually only a small fraction of a volt, may be necessary to minimize microphonics.

**Direction of current should be such that a north-seeking pole is attracted to the image end of the focusing coil, with the indicator located outside of and at the image end of the focusing coil.

Adjust to produce flattest field with maximum response. Alignment is correct when the center of the picture merely goes through focus and does not rotate when beam focus (Grid No. 4) is varied. For most commercial focus coils a 75-gauss field results from a focus-coil current of 75 milliamperes.

Z-7806

ENVIRONMENTAL

Shock: Per specification MIL-E-5272C (ASG) Paragraph 4.15.5 except:

A 12 impact shocks of 30g

B The shock shall be applied in the following directions:
1—Vertically perpendicular to longitudinal axis, 3 shocks in each direction.
2—Parallel to the minor horizontal axis, 3 shocks in each direction.

C The shock pulse width is defined by the use of a 0.2 to 250-cycle-per-second filter.

Vibration: (10g) Per MIL-E-5272C (ASG) Paragraph 4.7.12 Procedure XII except at operating temperature only. Center horizontal resolution at 3 x 10^{-5} maximum foot-candles, photocathode illumination will be at least 350 lines (EIA) with 5g applied acceleration in the frequency range from 50 to 500 cycles per second and a double amplitude of 0.036 inch from 5 to 50 cycles per second. Picture resolution of 350 TV lines (EIA) is defined as readable through any interference that may occur.

Humidity: Per MIL-E-5272C (ASG) Paragraph 4.4.1 Procedure 1. Following this test, the interelectrode insulation of the end pins 5, 6, 7, 8, 9, and 10 each with respect to all other end base pins grounded and with 350 volts (minimum) applied is greater than 500 ohms.

Acceleration: (70g) Constant acceleration when applied perpendicular to the longitudinal axis of the tube for 10 minutes.

OPERATING NOTES

Some magnesium-oxide targets may be damaged permanently if directly and intermittently exposed, while in operation, to extremely bright sources which cause high photoelectron densities to occur at the target. Such sources include the sun, photoflash lamps, and exploding wire flashes. Damage, if it does occur, takes the form of black image spots burned in the target by the intense light.

In most cases an 80-megohm, ¼-watt resistor in series with the photocathode in the camera will protect the tube. This resistor will not interfere with normal operation of these or other image orthicons which may be used in the modified camera.

If these or similar bright sources are to be observed continuously, appropriate exposure control of photocathode illumination can be supplied by neutral-density filters.

SPECIFIC PARAMETERS ON RECORDED DATA

All curves except spectral-sensitivity characteristics were recorded under the following conditions:

Camera Chain: General Electric TE-5 (modified)
Amplifier bandwidth—total 20 mc, flat to 6 mc

Resolution Chart: National Bureau of Standards Lens Test Chart, 100% contrast transparency.

Window Chart: 100% contrast, 1% area window for signal-noise and transfer characteristic data.

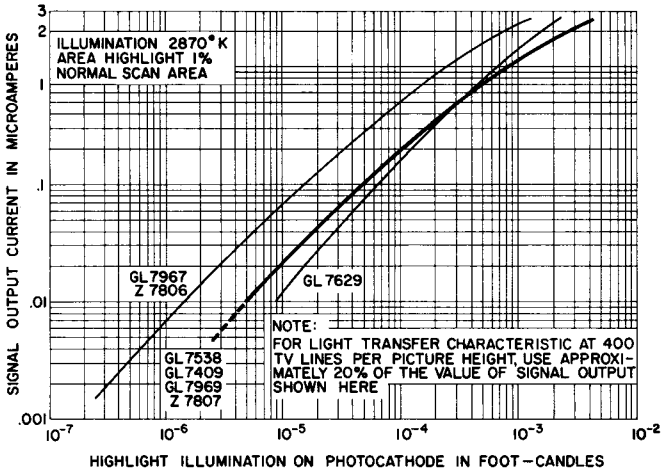
Light Source: 2870^0 Kelvin—tungsten

Light Level: Aperture and neutral density controlled (within specially constructed low-light-level box) to provide range from 10^{-8} to 10^{-2} foot-candles illumination on photocathode. For corresponding scene brightness in foot-lamberts when using Leitz f/1.5 lens (85 mm), multiply photocathode illumination in foot-candles by 12.

Operating Temperature for Image End: 25 to 30 C.

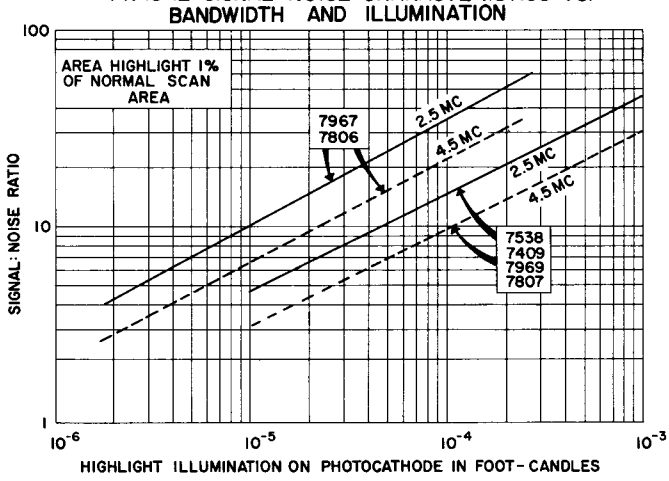
Target Raster: Target diameter is 1.40 inches. For corners of scanning raster just touching target edge raster dimensions are:

Aspect Ratio	Horizontal	Vertical
1 x 1 (square)	0.99″	0.99″
4 x 3 (standard)	1.12″	0.84″



Horizontal TV lines = 1.12 x TV lines per target inch

Vertical TV lines (EIA) = 0.84 x TV lines per target inch



Resolution sensitivity data is recorded in TV lines per target inch

Therefore, 700 TV lines per target inch = 784 horizontal lines
= 588 vertical lines (EIA)

IMAGE ORTHICON

FOCUS—MAGNETIC **DEFLECTION—MAGNETIC**

The GL-7967 is an image orthicon with an S-20 photosurface. This photosurface has a sensitivity two to three times that of the S-10 with an improved red response and lower thermionic noise. Because of the low gamma, the tube has a very wide operating range at low light levels.

This tube features a high-gain, thin-film, magnesium-oxide target with a sensitivity twenty to fifty times that of glass-target tubes such as the 5820. This target has several advantages. Its extreme thinness and anisotropic property virtually eliminate sideways leakage, which increases the resolution 25 to 50 percent over that of the standard target. It adapts the tube for service where the signal is stored for long periods before being read off, which permits additional sensitivity by use of low frame rates or by beam pulsing. It completely eliminates both stickiness and burn-in since operation depends on electron conduction, which is not a depletion process, rather than on ion conduction. The curve shown on page 3 compares the resolution sensitivity of the 7967 with that of a 5820 with equivalent photocathode.

The target characteristics also assure a higher amplitude response than that of the 5820. Another advantage of the GL-7967 is a considerable reduction in the redistribution of target secondary electrons. This reduces image-edging effect, particularly at black-to-white transitions.

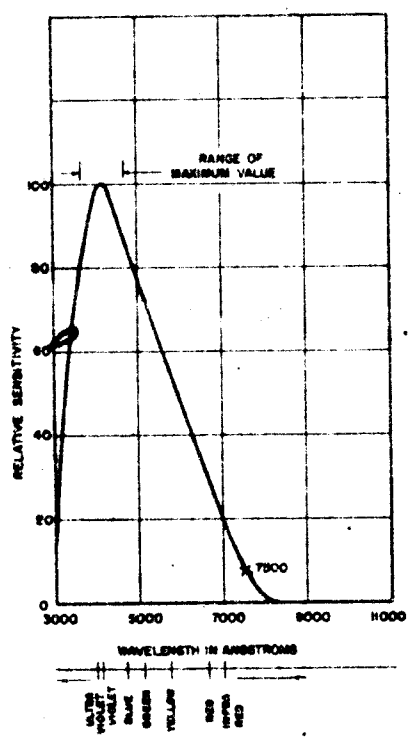
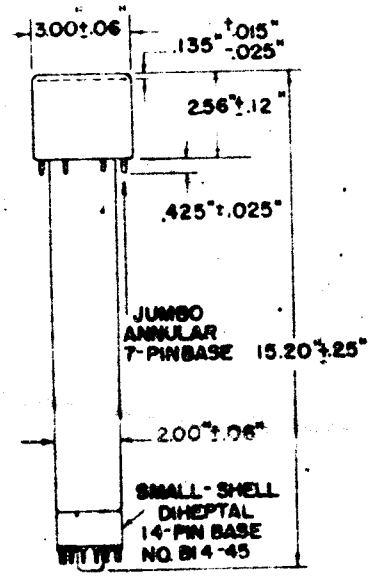
OPERATING NOTES

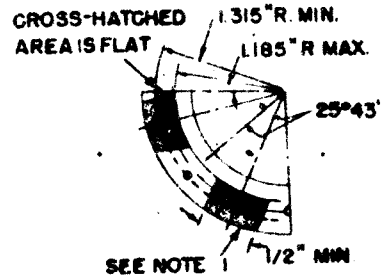
Normally a new tube will exhibit some slight after-image, characterized by a rapid and complete decay, which will gradually diminish with life. This can be minimized by use of an arbiter or by eliminating forced-air cooling for short periods of time.



Although a warm-up time of one hour is desirable, the tube can be used immediately after alignment as it cannot be damaged permanently by target burn-in.



Some tubes may exhibit microphonic bars if used immediately while relatively cool. These will disappear as the tube warms up and can be minimized during this period by slight readjustments in target voltage.



The target used in this tube greatly reduces the probability of permanent burn-in damage should a stationary highlight be imaged on the target for an extended period. However, imaging directly on the sun or other extremely bright sources should be avoided.

IMAGE ORTHICONS

FOCUS-MAGNETIC **DEFLECTION-MAGNETIC**

These low-light-level image orthicons are designed to meet a wide variety of requirements for industrial, military, and scientific applications. They provide an effective low-light-level sensitivity of 4 x 10^{-7} foot-candles photocathode illumination for resolution of 100 television lines per target-inch. The GL-7969 is designed for normal environmental operation. The Z-7807 is a ruggedized version especially designed to operate under severe shock and vibration conditions.

Both tubes feature a high-gain, thin-film magnesium-oxide target with a sensitivity ten to twenty times that of glass targets. The extreme thinness and the anisotropic property of this semiconductor target virtually eliminates lateral leakage and increases the resolution 25 to 50 percent over that of standard glass targets. Since operation of the target depends on electron conduction, which is not a depletion process, rather than on ion conduction, permanent stickiness and burn-in are virtually eliminated. Low gamma permits a very wide operating range.

These and other features of these image orthicons assure long life and reliable operation in such applications as medical biological studies, spectrographic detectors, underwater observation, and missile detection.

Target Temperature Range	15–55	15–55	C
Peak-to-Peak Blanking Voltage	5–20	5–20	Volts
Field Strength at Center of Focusing Coil**	75	75	Gausses
Field Strength of Alignment Coil, approximate#	0–3	0–3	Gausses

† Although these tubes will operate in standard equipment, modification to permit operation at these values will improve effective sensitivity for most applications.

‡ These values will permit the best low-light-level-sensitivity capability of the tube to be realized and will assure the maximum useful multiplier gain required in extreme low-light-level applications. The resolution sensitivity information in this data sheet was derived with these higher multiplier voltages.

§ Adjust to give the most uniformly shaded picture near maximum signal.

‖ 75 to 85 percent of photocathode voltage.

¶ The target supply voltage should be adjustable from −3 to +5 volts with blanking voltage off. Maximum target voltage is +10 volts above target cutoff. Recommended target voltage is +2 volts above cutoff. Slight readjustment, usually only a small fraction of a volt, may be necessary to minimize microphonics.

**Direction of current should be such that a north-seeking pole is attracted to the image end of the focusing coil, with the indicator located outside of and at the image end of the focusing coil.

Adjust to produce flattest field with maximum response. Alignment is correct when the center of the picture merely goes through focus and does not rotate when beam focus (Grid No. 4) is varied. For most commercial focus coils a 75-gauss field results from a focus-coil current of 75 milliamperes.

Z-7807

ENVIRONMENTAL

Shock: Per specification MIL-E-5272C (ASG) Paragraph 4.15.5 except:

A 12 impact shocks of 30g

B The shock shall be applied in the following directions:
1—Vertically perpendicular to longitudinal axis, 3 shocks in each direction.
2—Parallel to the minor horizontal axis, 3 shocks in each direction.

C The shock pulse width is defined by the use of a 0.2 to 250-cycle-per-second filter.

Vibration: (10g) Per MIL-E-5272C (ASG) Paragraph 4.7.12 Procedure XII except at operating temperature only. Center horizontal resolution at 3 x 10^{-5} maximum foot-candles, photocathode illumination will be at least 350 lines (EIA) with 5g applied acceleration in the frequency range from 50 to 500 cycles per second and a double amplitude of 0.036 inch from 5 to 50 cycles per second. Picture resolution of 350 TV lines (EIA) is defined as readable through any interference that may occur.

Humidity: Per MIL-E-5272C (ASG) Paragraph 4.4.1 Procedure 1. Following this test, the interelectrode insulation of the end pins 5, 6, 7, 8, 9, and 10 each with respect to all other end base pins grounded and with 350 volts (minimum) applied is greater than 500 ohms.

Acceleration: (70g) Constant acceleration when applied perpendicular to the longitudinal axis of the tube for 10 minutes.

OPERATING NOTES

Some magnesium-oxide targets may be damaged permanently if directly and intermittently exposed, while in operation, to extremely bright sources which cause high photoelectron densities to occur at the target. Such sources include the sun, photoflash lamps, and exploding wire flashes. Damage, if it does occur, takes the form of black image spots burned in the target by the intense light.

In most cases an 80-megohm, ¼-watt resistor in series with the photocathode in the camera will protect the tube. This resistor will not interfere with normal operation of these or other image orthicons which may be used in the modified camera.

If these or similar bright sources are to be observed continuously, appropriate exposure control of photocathode illumination can be supplied by neutral-density filters.

SPECIFIC PARAMETERS ON RECORDED DATA

All curves except spectral-sensitivity characteristics were recorded under the following conditions:

Camera Chain: General Electric TE-5 (modified)
Amplifier bandwidth—total 20 mc, flat to 6 mc

Resolution Chart: National Bureau of Standards Lens Test Chart, 100% contrast transparency.

Window Chart: 100% contrast, 1% area window for signal-noise and transfer characteristic data.

Light Source: 2870^0 Kelvin—tungsten

Light Level: Aperture and neutral density controlled (within specially constructed low-light-level box) to provide range from 10^{-8} to 10^{-2} foot-candles illumination on photocathode. For corresponding scene brightness in foot-lamberts when using Leitz f/1.5 lens (85 mm), multiply photocathode illumination in foot-candles by 12.

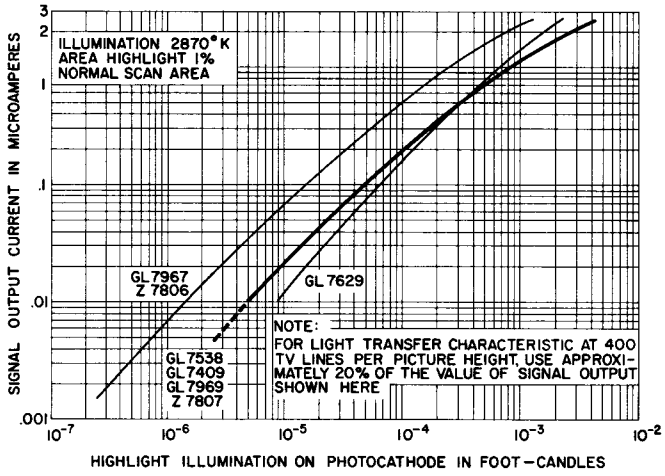
Operating Temperature for Image End: 25 to 30 C.

Target Raster: Target diameter is 1.40 inches. For corners of scanning raster just touching target edge raster dimensions are:

Aspect Ratio	Horizontal	Vertical
1 x 1 (square)	0.99″	0.99″
4 x 3 (standard)	1.12″	0.84″

Horizontal TV lines = 1.12 x TV lines per target inch

Vertical TV lines (EIA) = 0.84 x TV lines per target inch



Resolution sensitivity data is recorded in TV lines per target inch

Therefore, 700 TV lines per target inch = 784 horizontal lines
= 588 vertical lines (EIA)

IMAGE ORTHICON

FOCUS—MAGNETIC **DEFLECTION—MAGNETIC**

The GL-7969 is an image orthicon with an ultraviolet-sensitive photosurface. Because of the low gamma, the tube has a very wide operating range at low light levels.

This tube features high gain, thin film magnesium oxide target with a secondary-emission ratio of twenty times that of signal-type target tubes such as the 5820. This target has several advantages. Its extreme hardness and insensitivity to moisture practically eliminate sideways leakage, which increases the resolution 25 to 50 percent over that of the standard target. It also [illegible] the charge values [illegible] being read off, which permits [illegible] signal-to-noise ratio by use of low frame rates or slow scanning. It completely eliminates both sticking and burn-in since operation depends on electron conductivity rather than a depletion process. Lateral conduction is also [illegible].

The target characteristics also assure a higher sensitivity response than that of the 5820. Another advantage of the GL-7969 is a considerable reduction in the redistribution of target secondaries. This reduces image [illegible] and [illegible] dark-area [illegible] black-to-white [illegible]

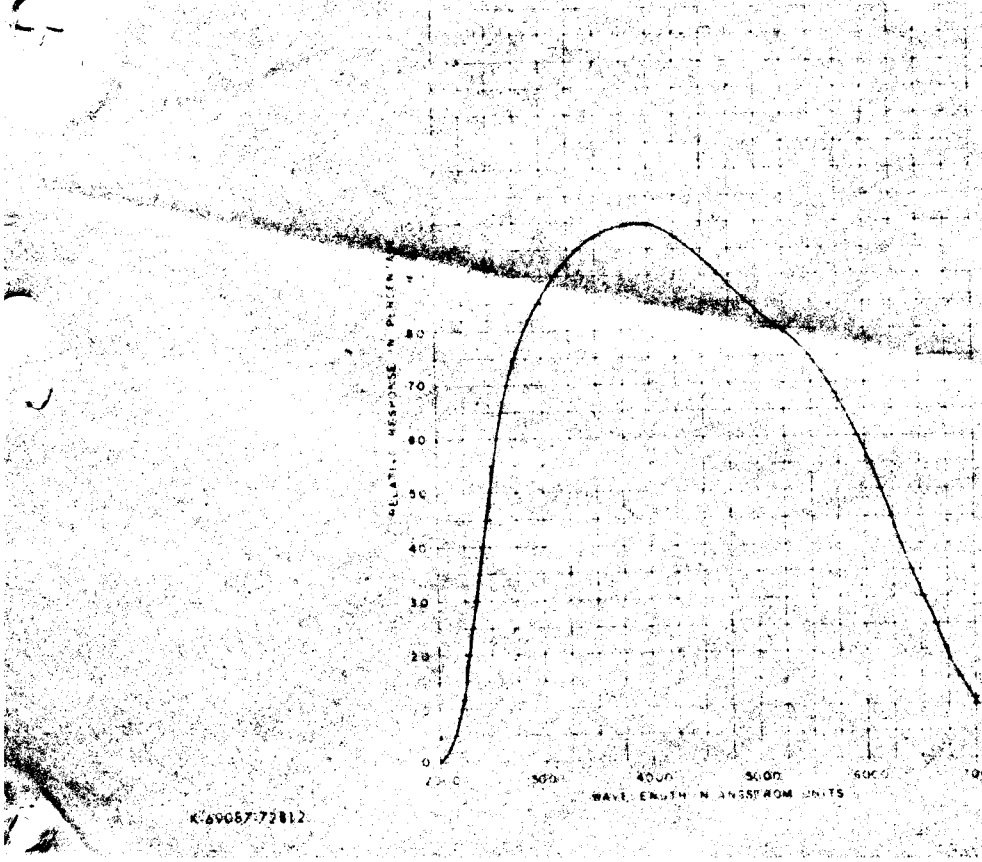
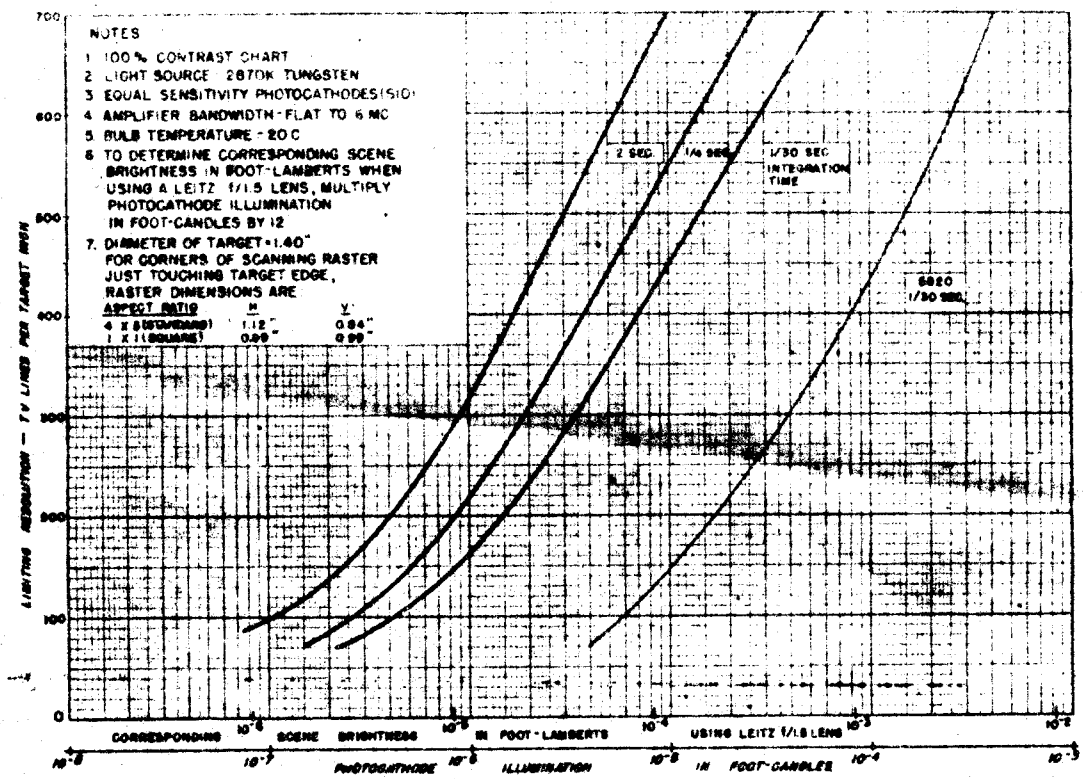
[3] Direction of current should be such that a north-seeking pole is attracted to the image end of the focusing coil when the deflection coil is located outside of and at the image end of the focusing coil.



OPERATING NOTES

Normally a new tube will exhibit some slight "after-image" characterized by a rapid exponential decay which will gradually diminish with life. This can be minimized by use of an erase or fast-sweeping focused-raster scanning for short periods of time. Although a warm-up time of one hour is desirable, the tube can be used immediately after alignment as it cannot be permanently burned by target burn-in.

Some tubes may exhibit spurious bursts of signal immediately while relatively cool. These will disappear as the tube warms up and can be minimized during this period by slight readjustment of target voltage.



The target used in this tube greatly reduces the probability of permanent burn-in damage should a stationary highlight be imaged on the target for an extended period. However, imaging directly on the sun or other extremely bright sources should be avoided.

PACKAGED VOLTAGE-TUNABLE MAGNETRON

2750-3090 MEGACYCLES — 1.00-WATT OUTPUT

The ZM-6205 is a voltage-tunable magnetron with integral load isolator for voltage-tunable operation in the 2750-3090 megacycle frequency range. It is a complete r-f power source package requiring only input power connections and an r-f power-output connection and has a minimum CW power output of 1.00 watt across the entire frequency range. The tube may be voltage tuned over a portion or all of the frequency range for which it is designed.

The ZM-6205 has a noise level of -95 decibels with respect to carrier, a power variation limited to 1.2 decibels over its entire frequency range and is environmentalized for airborne applications.

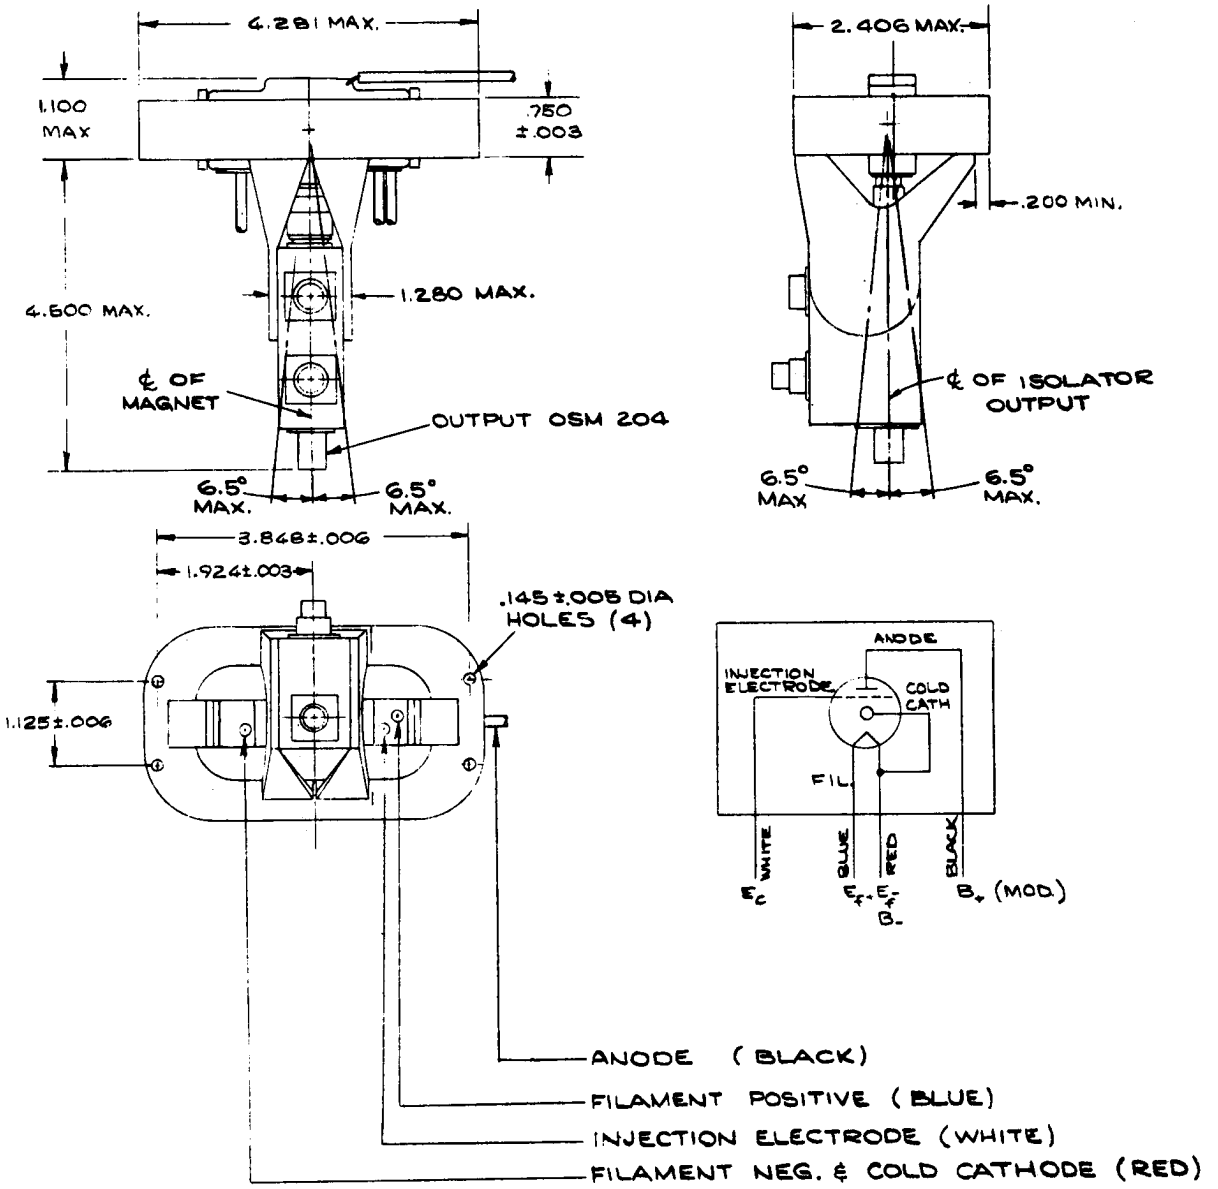
Power Variation ‡	1.2	Decibels
Dynamic Tuning Rate Variation	±5	Percent

The specifications of this type are subject to change. Delivery of samples and the existence of these data do not imply continued availability of types with the same characteristics or dimensions. For the most recent information concerning the status of this device, please consult your local Tube Department Regional Sales Office.

* Filament current should be adjusted to 2.0 amperes.

Frequency controlled by anode voltage.



† This noise level is measured with respect to carrier level, 30 mc away from carrier.

‡ Measured across the entire frequency band and over a -55 C to +95 C magnet temperature range.

NOTE: Since a change in anode voltage of one volt produces a frequency change of approximately 3.35 megacycles, the anode supply should have sufficiently low ripple and high regulation to prevent an excess of frequency modulation.

CAUTION: A clearance of 6 inches between ferromagnetic materials and the tube will prevent serious change of the operating characteristics.

PACKAGED VOLTAGE-TUNABLE MAGNETRON

2000-4000 Megacycles — 1.0 Watt CW Output

The ZM-6222 is a magnetically shielded voltage-tunable oscillator which operates at a minimum power output of one watt over the 2000 to 4000-megacycle frequency range. Unlike conventional electron devices employing magnetic fields, this shielded VTM is unaffected by passive magnetic materials. It does not require special tools, storage facilities or handling other than that normally given to a non-magnetic electron device. This shielded VTM also incorporates RFI shielding to attenuate stray radio-frequency on the d-c leads to levels below -40 dbc. It is a complete radio-frequency power source which requires only d-c input power and generates radio-frequency power over its electronically tuned octave frequency range. This voltage-tuned magnetron may be operated over a portion or all of the frequency range or operated at a fixed frequency. Its frequency versus voltage-tuning characteristic is essentially linear.

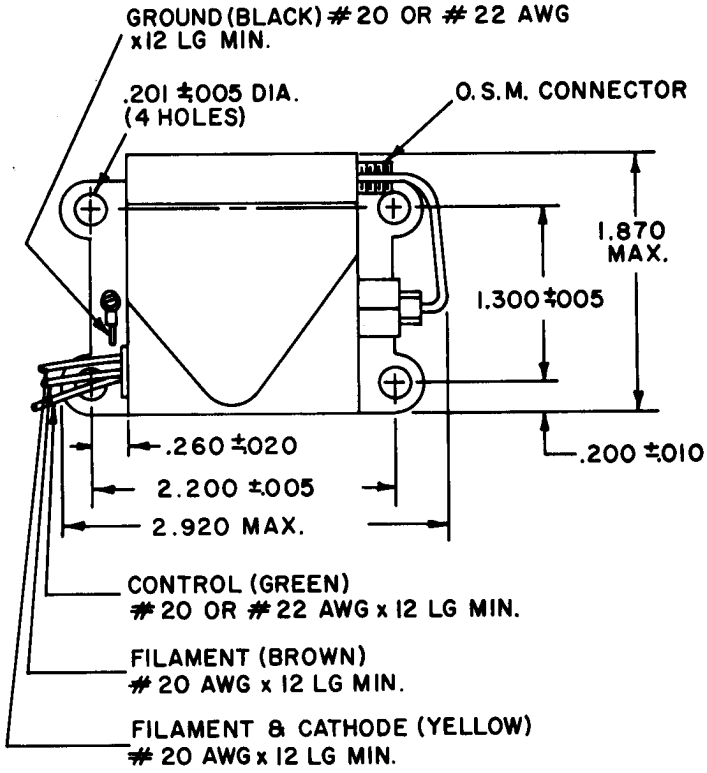
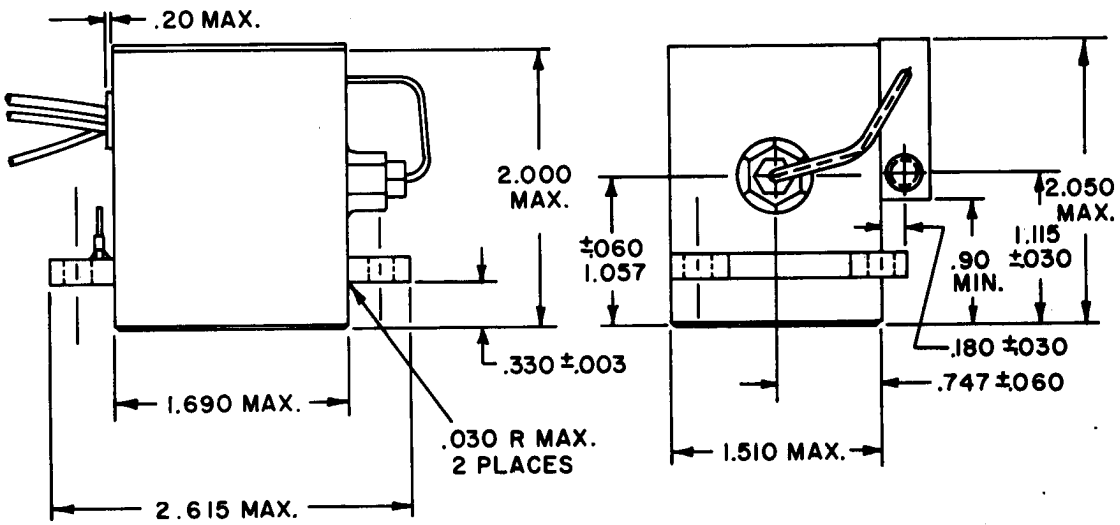
Power Output, Minimum	10.0	Watts
Noise †	-80	Decibels per Megacycle



* Filament voltage should be adjusted to provide a filament current of 3.0 amperes under broadband swept oscillating conditions.



\# Frequency controlled by anode voltage.

The specifications of this type are subject to change. This device is now under development and is made available for experimental purposes only. For the most recent information concerning the status of this development, please consult your local Tube Department Regional Sales Office, or current Preliminary Technical Information for the same catalog number.

NOTE: Since a change in anode voltage of one volt produces a frequency change of approximately 1.8 megacycles, the anode supply should have sufficiently low ripple and high regulation to prevent an excess of frequency modulation.

† Measured at 1.5 megacycles away from carrier with respect to carrier power level. This is an optional parameter which is included on special order only.

ZM-6276

PACKAGED VOLTAGE-TUNABLE MAGNETRON

2600-3200 Megacycles — 100 Watts Minimum CW Output

Integral Magnet and Isolator

The ZM-6276 is a magnetically shielded voltage-tunable oscillator which operates at a minimum power output of 100 watts over the 2600 to 3200-megacycle range. It is designed for CW/FM transmitting-tube operation at low- or high-modulation frequencies. The high efficiency allows air cooling to be used and in many applications heat-sink cooling is adequate. The integral isolator protects the tube against load mismatches thus minimizing interface problems between the VTM and its associated equipment.

This shielded tube is unaffected by passive magnetic materials and does not require the special tools, storage and handling necessitated by conventional electron devices employing magnetic fields. It is a complete radio-frequency power source which requires only d-c input power and generates radio-frequency power over its electronically tuned frequency range. This voltage-tuned magnetron may be operated over a portion or all of the frequency range or operated at a fixed frequency. Its frequency versus voltage-tuning characteristic is essentially linear.

ZM–6287

INDUSTRIAL HEATING MAGNETRON

918 Megahertz
Forced-Air Cooled

1000 Watts Output Power
Integral Series Field Coils

The ZM–6287 is a low-voltage CW magnetron assembly for use in the 915-MHz ISM Band for microwave heating applications. It is designed for operation from a low cost, voltage doubler circuit, connected to a 240-volt a-c line. Approximately 50 volts a-c boost from an autotransformer is needed to achieve the 1000-watt output(Fig. 1). It contains an integral electromagnet energized by the voltage doubler output(series connection). The r-f output line contains a d-c bypass arrangement which allows the body of the tube to run off ground.

Grounded-Grid Operation

Heat-Sink and Forced-Air Cooled
Metal and Ceramic

The ZP-1015 is a heat-sink-cooled version of the GL-7399 especially designed for pulsed-amplifier or oscillator service at L-band frequencies. This tetrode is particularly well suited for use in airborne IFF radar equipment.

The tube is capable of providing useful output at frequencies up to approximately 1500 megacycles.

Features of the ZP-1015 include long life and reliability, long pulse width and high gain.

GRID-PULSED OSCILLATOR-CLASS C

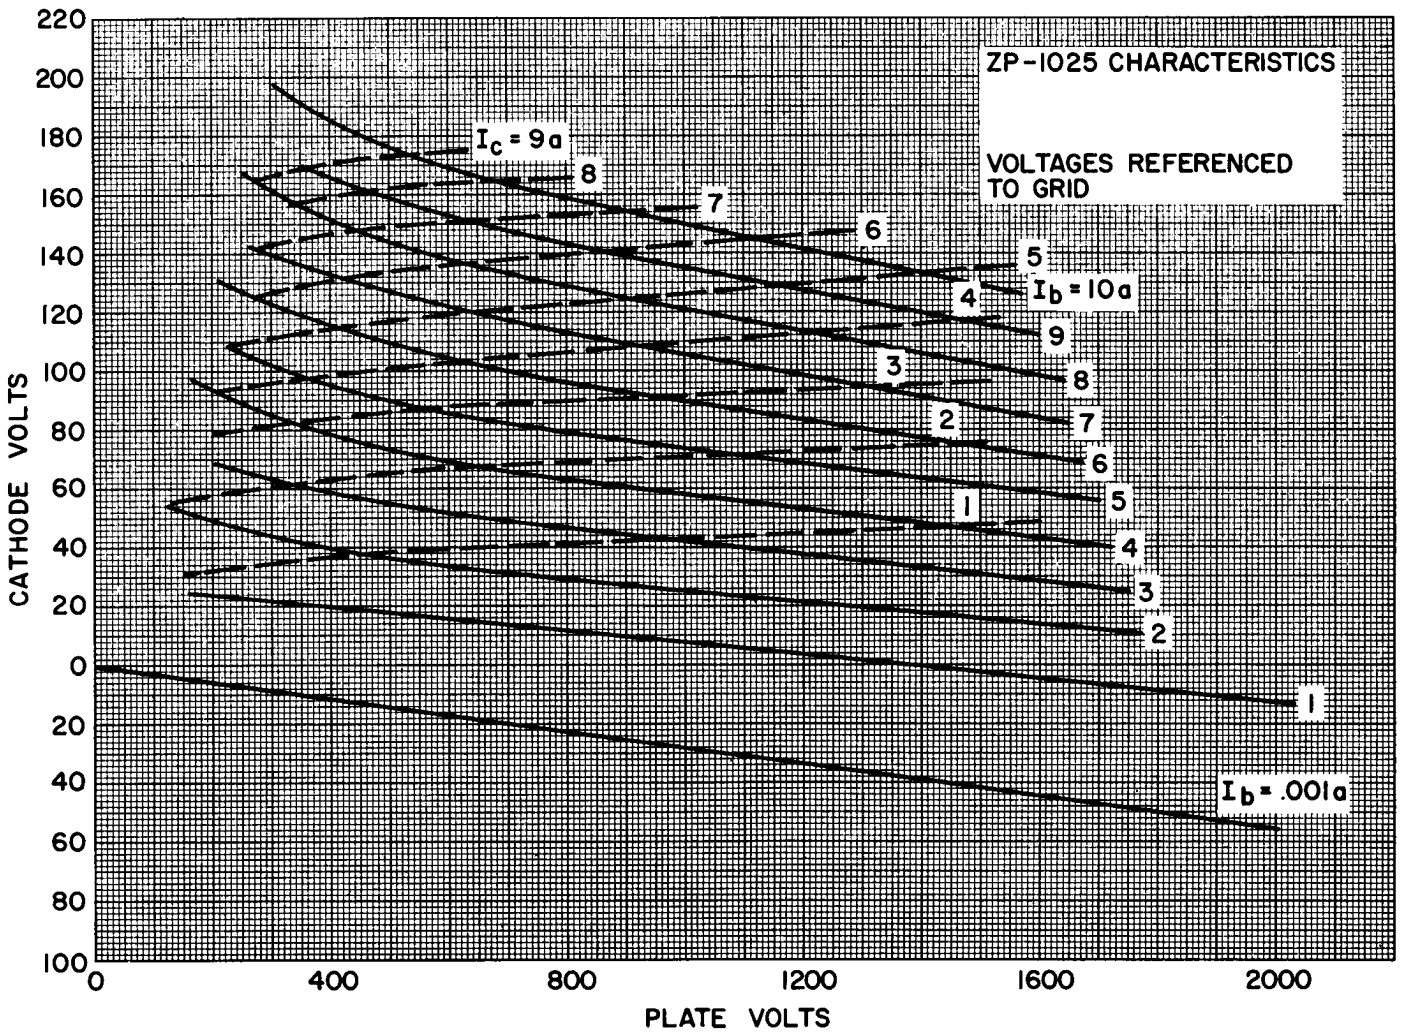
Maximum Ratings

DC Plate Voltage	2.5	Kilovolts
DC Plate Current, During Pulse	3.0	Amperes
DC Grid Voltage	−200	Volts
Plate Dissipation	110	Watts
Pulse Width♦	15	Microseconds
Duty Factor ϕ	0.02	

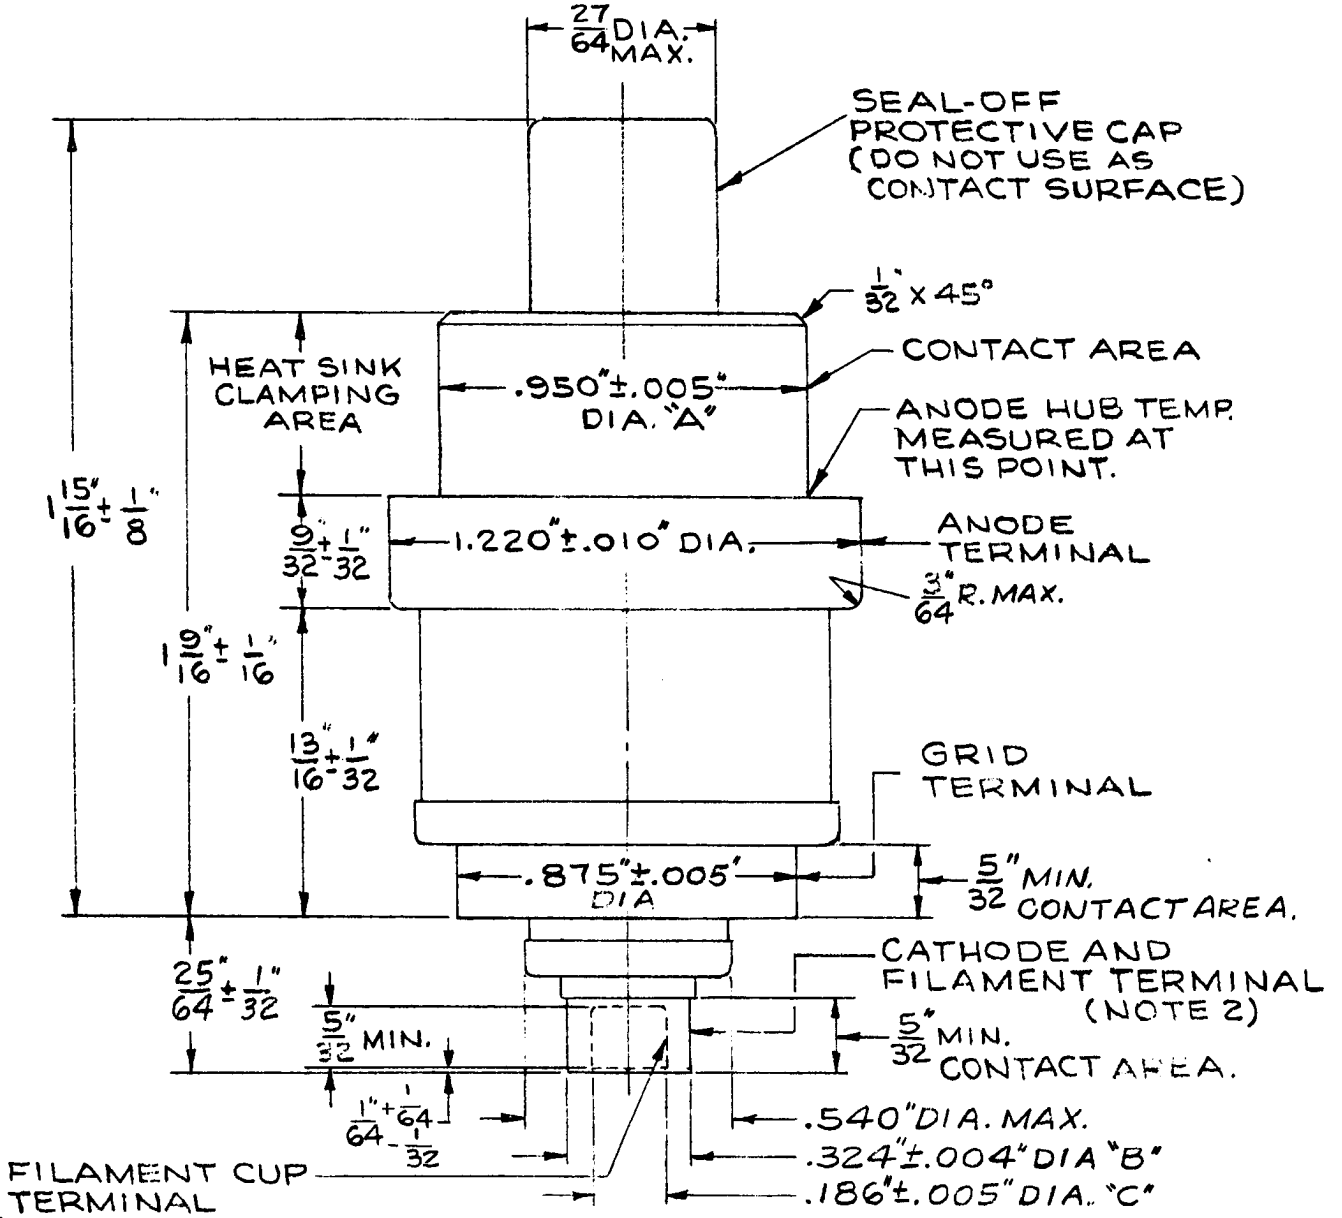
Typical Operation

Grounded-Grid Circuit at 1100 Megacyles, ¼ λ Output

DC Plate Voltage	1750	1950	2200	Volts
DC Plate Current, During Pulse	2.2	2.6	2.7	Amperes
DC Grid Voltage Supply**	−97	−104	−104	Volts
DC Grid Current, During Pulse	1.05	1.2	1.25	Amperes
Power Output, During Pulse (Useful)	1.5	2.0	2.4	Kilowatts
Pulse Width	10	10	10	Microseconds
Duty Factor	.02	.02	.02	



* Because of back-heating due to transit time effects, it may be necessary to reduce the heater voltage. For the 1100 mcs, 2 kw, .02 duty condition, the typical heater voltage is 5.5 volts.



§ A suitable heat-sink clamping arrangement must be provided to limit the anode hub temperature to the value specified.

◊ Pulse duration is measured between points at 70 percent of the peak value. The peak value is defined as the maximum value of a smooth curve through the average of the fluctuations over the top portion of the pulse.

ϕ Maximum ratio of on-time to elapsed time during any 1-millisecond period.

** With a series grid resistance of 50 ohms.

CONCENTRICITIES:

The following total indicator readings are measured with respect to a centerline determined by the centers of the anode terminal and control grid terminal.

Diameter A - 0.030 inches
Diameter B - 0.036 inches
Diameter C - 0.042 inches

Total indicator reading of filament cup terminal diameter (C) measured with respect to center of cathode and filament terminal diameter (B) - 0.016 inches.

TETRODE

Pulsed Service
Grounded-Grid Operation

Water Cooled
Metal and Ceramic

Integral Water Jacket

The ZP-1034 is a small-size, four-electrode transmitting tube especially designed for pulsed-amplifier service at L-band frequencies. This tetrode is particularly well suited for use in ground-based equipment such as steerable array radar.

The tube is capable of providing useful output at frequencies up to approximately 1500 megacycles.

Features of the ZP-1034 include long life and reliability, long pulse width, high gain and broad-banding capability.

These together with such design factors as an oxide-coated cathode, coaxial elements, and metal-ceramic construction make the tube well adapted to application in modern systems where performance and reliability are important.

ZP-1044
TETRODE

Internal Feedback for CW Oscillator Service
Grounded-Grid Operation

Forced-Air Cooled
Metal and Ceramic

The ZP-1044 is a forced-air cooled power tetrode especially designed for CW oscillator service through approximately 1250 megacycles. This tube is particularly well suited for use in special applications such as a high level RF power source operating over the range of 200 to 1000 megacycles.

The tube features internal feedback which eliminates the need for the complicated external circuit arrangements normally required in oscillator service. This special feature greatly simplifies cavity design, construction, and operation, particularly where very broad frequency coverage is required.

Other features include metal and ceramic construction, an integral radiator capable of dissipating 1500 watts and an indirectly heated thoriated tungsten cathode.

ZR-7512

TRIGGERED VACUUM GAP

45 Kilovolts
50,000 Amperes
15,000 Joules

Fires at 300 Volts
Ceramic Envelope

The ZR-7512 is a cold-cathode, vacuum, triggered spark gap capable of switching 15,000 joules at high voltage. Unique design combines the desirable features of vacuum and gas devices. These include extremely wide voltage range, ease of triggering, high voltage capability, rapid recovery time, stability of characteristics and reliability.

Although capable of withstanding a hold-off voltage of 55 kilovolts indefinitely, the ZR-7512 will fire reliably at voltages as low as 300 volts. It will reliably switch non-repetitive high-current pulses with minimum delay and jitter in high-voltage circuits. Applications include "crowbars"* and switching stored electrical energy systems into low-impedance loads, or energy-storage capacitors into resistive or inductive loads.

ELECTRICAL

Heater Voltage	None Required

MECHANICAL

Mounting Position – Any	
Net Weight	Approx. 4 lbs.

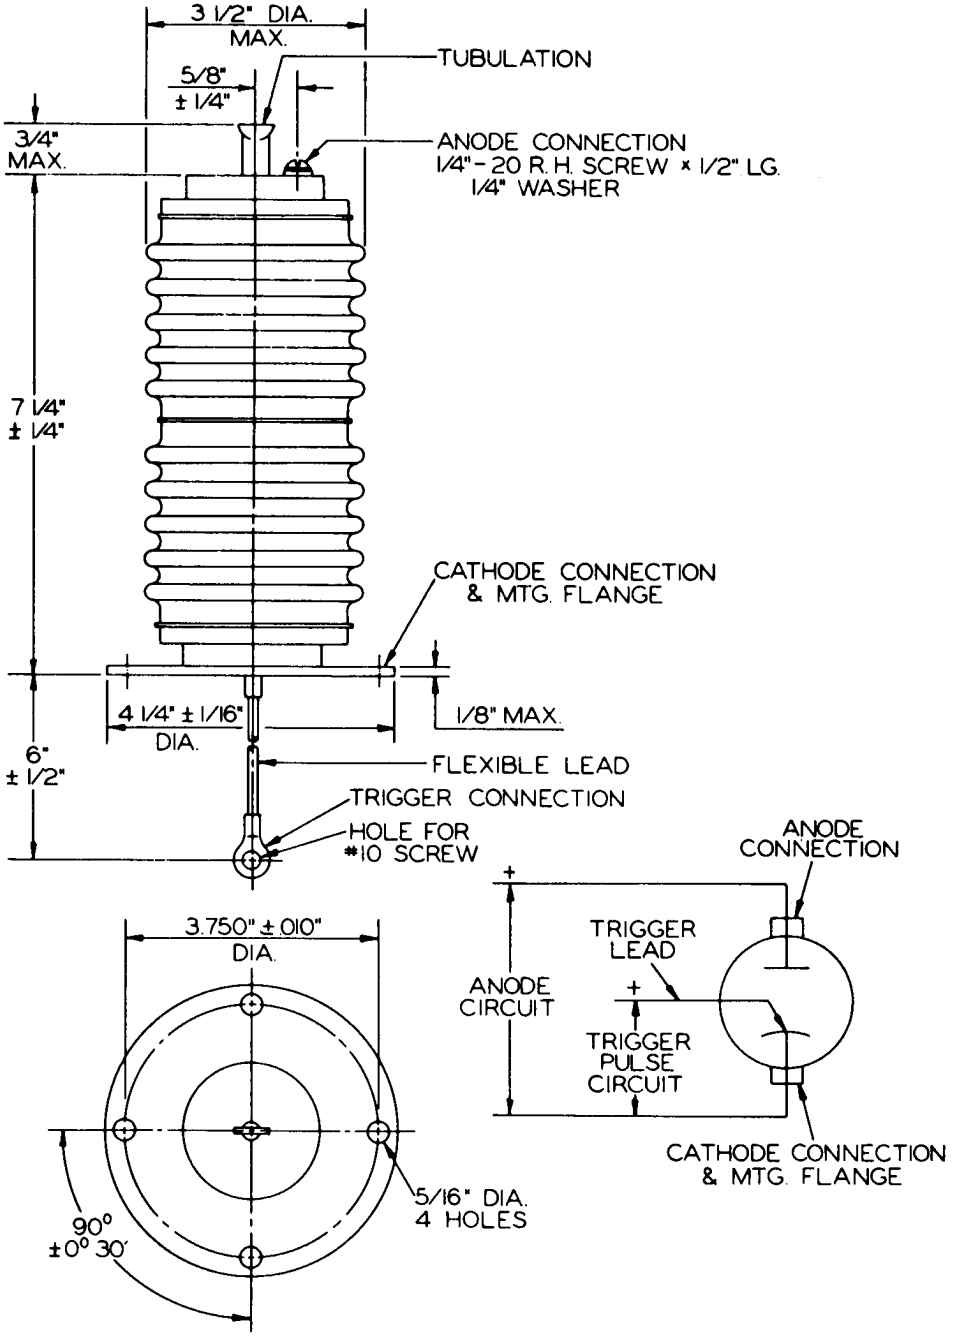
MAXIMUM RATINGS

Interelectrode Leakage Resistance	10,000	Megohms
Main Gap		
Operating Voltage	300V to 45	Kilovolts
Hold-Off Voltage, Indefinite Time, minimum	55	Kilovolts
Peak Current		
Unidirectional Pulse, maximum	50,000	Amperes
Charge Conducted Through Gap per Operation**, maximum	0.7	Coulombs
Discharge Rate, maximum	2	Per Minute
Delay Time †, V app. = 45 KV, maximum	0.1	Microseconds
Jitter †, V app. = 45 KV, maximum	0.1	Microseconds
Trigger Gap		
Typical Trigger Firing Circuit:		
Peak Voltage ‡, typical	5	Kilovolts
Short-Circuit Current ¶, typical	40	Amperes

* In a "crowbar" application the gap acts as a short-circuiting switch to protect vulnerable high-voltage equipment by removing the direct-current supply voltage within tenths of a microsecond after initiation of the trigger-pulse. Unless the fault is self-clearing, the circuit must subsequently be opened in the usual manner.

** This rating refers to the charge originating from the capacitor bank. For further information concerning "follow-thru" current from the power supply in a given application consult the General Electric Microwave Tube Business Section.

† From trigger-gap breakdown to main-gap breakdown.



‡ The voltage rise time should be as fast as is consistent with the firing speed and accuracy required. The trigger will fire typically at 1 to 3 kilovolts on the leading edge of the pulse but may fire at lower trigger voltages. Only pulse voltage shall be applied to the trigger.

¶ Delay time and jitter may be decreased and gap life increased by increasing trigger short-circuit current. Currents up to 100 amperes may be used. The pulse width should preferably not exceed 2 microseconds.

The specifications of this type are subject to change. This device is now under development and is made available for experimental purposes only. For the most recent information concerning the status of this development, please consult your local Tube Department Regional Sales Office, or current Preliminary Technical Information for the same catalog number.

OPERATING NOTES

When discharging or crowbaring energy-storage capacitors, repetitive firing for short periods may be necessary to maintain sufficiently low voltage to protect electrical equipment until circuit is cleared. Restoration of power-supply voltage to maintain service continuity without circuit-breaker action after a self-clearing fault is feasible in a typical circuit by blocking the trigger pulse. This is due to the rapid deionization time and excellent voltage recovery capability of the ZR-7512. For further information consult the Microwave Tube Business Section, Bldg. 269, Schenectady, New York, FRanklin 4-2211, Extension 5-2507.
