Average Direct Interelectrode Capacitances

Grid to plate.	2.8 $\mu\text{f.}$
Grid to heater and cathode.	3.4 $\mu\text{f.}$
Plate to heater and cathode.	2.6 $\mu\text{f.}$

Heater Rating

Heater voltage.....	10.0 volts, a.c. or d.c.
Nominal heater current.....	0.32 ampere

The heater element of this tube is designed to operate on a voltage basis and should be operated at as near the rated voltage as is practicable.

Cathode Connection—When the heater is operated on alternating current, a reduction of hum in the tube may usually be obtained by connecting the cathode to a center tap on the secondary of the heater transformer or to the center point of a suitable resistance connected across the heater terminals. If voltage must be applied between the heater and cathode, it should be kept as low as possible and should never exceed 90 volts.

Characteristics—Plate current characteristics of a typical 272A tube are shown in Figure 3 as functions of grid voltage for several values of plate voltage. Corresponding amplification factor, plate resistance, and transconductance characteristics are given in Figures 4, 5 and 6, respectively. Plate current characteristics are shown as functions of plate voltage for several values of grid voltage in Figure 7.

Operating Conditions and Output—Permissible operating conditions are included within the area, ABCD, in Figure 3. Amplification factor, plate resistance, transconductance, and performance data are given in the table below for a number of typical operating conditions represented by selected points within this area. The less severe operating conditions should be selected in preference to maximum operating conditions wherever possible. The life of the tube at maximum conditions may be shorter than at less severe conditions.

The performance data include the fundamental power output in milliwatts and the second and third harmonic levels in decibels below the fundamental for values of load resistance, R , both equal to and double the plate resistance, r_p . The peak value of the sinusoidal input, E_{gm} , which gives the indicated power output, P_m , and harmonic levels, F_{2m} and F_{3m} , in each case, is numerically equal to the grid bias. For a smaller input voltage, E_g , the output and harmonic levels, except for the lowest third harmonic levels, are given approximately by the following relations:

$$P = P_m \left(\frac{E_g}{E_{gm}} \right)^2$$

$$F_2 = F_{2m} + 20 \log_{10} \frac{E_{gm}}{E_g}$$

$$F_3 = F_{3m} + 40 \log_{10} \frac{E_{gm}}{E_g}$$

The level of the third harmonic in the 272A tube is usually low and may differ widely in individual tubes. The values given in the table are for a typical tube.

Microphonic Noise—With a plate voltage of 100 volts, a grid bias of -7 volts, and a load resistance of 100,000 ohms, the mean microphonic noise output level of the 272A tube, measured in a laboratory reference test set, is 39 decibels below 1 volt. The range of levels of individual tubes extends from 26 to 52 decibels. Since microphonic noise depends on the type and intensity of the mechanical disturbance which produces it, the values given here are useful chiefly for comparison with the levels of other tubes which have been tested in the same way.
