TWIN TRIODE

DESCRIPTION AND RATING

The 6SN7-GTB is a medium-mu twin triode suitable for use in a wide variety of general-purpose amplifier and phase-inverter applications. It is also especially useful as a blocking oscillator, multivibrator, or vertical-deflection amplifier in television receivers.

Electrically and physically the 6SN7-GTB is a replacement for the 6SN7-GTA. In addition, however, the 6SN7-GTB exhibits a controlled heater warm-up characteristic which makes the tube especially suited for use in television receivers which employ series-connected heaters. When the 6SN7-GTB is used in conjunction with other 600-milliamperere types which have essentially the same heater warm-up characteristic, heater voltage surges across the individual tubes are minimized during the warm-up.

Except for heater and heater warm-up time ratings, the 12SN7-GTA is identical to the 6SN7-GTB.

* Heater warm-up time is defined as the time required in the circuit shown at the right for the voltage across the heater terminals to increase from zero to the heater test voltage (V₁). For this type, E=25 volts (RMS or DC), V₁=5.0 volts (RMS or DC), and R=31.5 ohms.

† Without external shield.

‡ For operation in a 525-line, 30-frame television system as described in "Standards of Good Engineering Practice Concerning Television Broadcast Stations," Federal Communications Commission. The duty cycle of the voltage pulse must not exceed 15 percent of one scanning cycle.

§ Value given is to be considered as an Absolute Maximum Rating. In this case, the combined effect of supply voltage variation, manufacturing variation including components in the equipment, and adjustment of equipment controls should not cause the rated value to be exceeded.

⌘ In stages operating with grid-leak bias, an adequate cathode-bias resistor or other suitable means is required to protect the tube in the absence of excitation.

Note: Coupling capacitors (C) should be selected to give desired frequency response. R_k should be adequately by-passed.

Notes: 1. E_o is maximum RMS voltage output for five percent (5%) total harmonic distortion. 2. Gain measured at 2.0 volts RMS output. 3. For zero-bias data, generator impedance is negligible.
