Cooling, Conduction:

The plate terminal must be thermally coupled to a constant-temperature device (heat sink—solid or liquid) to limit the plate terminal to the specified maximum value of 250° C. The grid-No.2, grid-No.1, cathode, and heater terminals may also require coupling to the heat sink to limit their respective terminal temperature to the specified maximum value of 250° C.

^a Because the cathode is subjected to considerable back bombardment as the frequency is increased with resultant increase in temperature, the heater voltage should be reduced depending on operating conditions and frequency to prevent overheating the cathode and resultant short life.

^b Measured with special shield adapter.

^c Continuous Commercial Service.

^d Maximum plate dissipation is a function of the maximum plate input, efficiency of the class of service, and the effectiveness of the cooling system. See *Cooling, Conduction* under *General Data*, and also *Cooling Considerations*.

^e Averaged over any audio-frequency cycle of sine-wave form for *AP Power Amplifier & Modulator Service*.

^f If this value is insufficient to provide adequate bias, the additional required bias must be supplied by a cathode resistor or fixed supply.

Note 6: With dc plate voltage of 300 volts, dc grid-No.2 voltage of 150 volts, dc grid-No.1 voltage adjusted to give a dc plate current of 35 ma.

COOLING CONSIDERATIONS

The conduction-cooling system consists, in general, of a constant-temperature device (heat sink) and suitable heat-flow path (coupling) between the heat sink and tube. Careful consideration should be given to the design of a heat-flow path through a coupling device having high thermal conductivity.

Thermal conductivity⁹ may be calculated from the equation:

$$K = \frac{W}{A \frac{(T_2 - T_1)}{L}} \quad (1)$$

where:

- K = thermal conductivity of the material
- W = power transfer in watts
- A = area measured at right angles to the direction of the flow of heat in square inches
- T_1, T_2 = temperature in degrees Centigrade of planes or surfaces under consideration
- L = length of heat path in inches through coupling material to produce temperature gradient

⁹ Thermal conductivity is defined as the time rate of transfer of heat by conduction, through unit thickness, across unit area for unit difference of temperature. It is measured in watts per square inch for a thickness of one inch and a difference of temperature of 1° C.

For a given system Equation (1) must be integrated to consider changes in area (A) dependent on the coupling configuration and changes in thermal conductivity (K) dependent on various coupling materials and interfaces. Equation (1) may now be reduced to the following:

$$K_S = \frac{W_P}{T_2 - T_1} \quad (2)$$

where:

- K_S = thermal conductance of the system
- W_P = maximum permissible plate dissipation in watts
- T_2 = temperature in degrees Centigrade at tube terminal
- T_1 = temperature in degrees Centigrade of heat sink

UNIPOTENTIAL CATHODE

The 7870 is the same as the 7801 except for the following items:

Heater, for Unipotential Cathode:

Voltage (AC or DC)^a. 6.3 ± 10% volts
 Current at heater volts = 6.3. 1 amp

^a Because the cathode is subjected to considerable back bombardment as the frequency is increased with resultant increase in temperature, the heater voltage should be reduced depending on operating conditions and frequency to prevent overheating the cathode and resultant short life.
